The commenter is correct that the DEIS counted emissions benefits that occur internationally during crude-oil transport to the United States, rather than just counting the domestic benefits of reduced refinery and fuel-distribution emissions. For the FEIS emissions estimates, NHTSA has revised the upstream emissions factors to reflect the assumption that 90 percent of the reduction in domestic fuel refining reduces imports of crude petroleum (and, thus, does not reduce domestic emissions from petroleum extraction or transportation), while only the remaining 10 percent reduces domestic production of crude petroleum (and, thus, reduces emissions during both petroleum extraction and transportation). NHTSA estimated these percentages by comparing U.S. fuel consumption and petroleum imports under several scenarios from EIA's Annual Energy Outlook (EIA 2008a).

The commenter is also correct that the emissions factors in GREET for heavy-duty truck, rail, and barge do not reflect the latest round of EPA emissions standards (the heavy-duty highway 2007/2010 standards). NHTSA coordinated with EPA to update the emissions factors for heavy-duty truck, rail, and barge processes. NHTSA updated these emissions factors in the modeling for the FEIS. The emissions reductions due to decreases in the amount of transportation and distribution of fuel now reflect the most current emissions factors.

Commenter: Susan Bromm

Page 3-20: For the section on treatment of incomplete or unavailable information, EPA recommends the following addition, indicating the limitations of the modeling done for upstream emissions of MSATs:

"Data used to estimate upstream emission impacts on air toxics are significantly older than data for criteria pollutants and use of more recent and complete data could affect results. In addition, all upstream toxic emissions were assigned to refinery processes, which could lead to over assignment of air toxic emissions to areas with refineries and an under assignment to areas without them."

Page 3-23 indicates that upstream MSAT emissions were estimated using the DOE [U.S. Department of Energy] GREET model. However, GREET does not include toxics, although in 2000, a version of GREET was developed which estimated air toxics using speciation factors. EPA assumes this was what was used. If that is the case, there are significant limitations which should be discussed. First, ethanol production is not included in the model. The model also used combustion emission factors for vehicles used in transport that are now significantly out of date, and assumed evaporative emissions of benzene were equivalent to levels of benzene in fuel. For refinery processes, the emission factors used are very old. As part of its analyses for last year's draft proposed greenhouse gas rule, and the upcoming rule implementing requirements under EISA, EPA developed air toxic emission factors for upstream processes using the most recent available information. We recommend that NHTSA coordinate with EPA on updating upstream toxic emission factors.

Also, all upstream toxic emissions were assigned to refinery processes. EPA does not believe this assumption is reasonable as it means that there will be an over assignment of emissions to areas with refineries and an under assignment to areas without them.

Page 3-25: In Section 3.3.2.2 "Results of the Emissions Analysis," the text states "As discussed in Section 3.31, pollutant emissions from vehicles have been declining since 1970 and EPA projects that they will continue to decline. This trend will continue regardless of the alternative that is chosen for future CAFE standards" (p. 3-25). A similar statement is in Section 3.3.2.3.2 (p. 3-28): "As with the criteria pollutants, current trends in the levels of air toxics emissions would continue, with emissions continuing to decline due to the EPA emission standards despite a growth in total VMT." In fact, Tables 3.3-3 and 3.3-5 show increases in VOC between 2025 and 2035 (and in the case of DPM, emissions increase in each analysis year in all scenarios, including No Action). The incorrect statements in the text should be deleted, and the trend of increasing emissions in the later analysis years should be acknowledged.

Response

NHTSA has clarified the discussion of upstream air toxic emissions in the FEIS. The following paragraphs respond to the commenter's individual points:

Page 3-20: The commenter is correct that NHTSA assigned all upstream toxic emissions to refinery processes, and that this results in an over-assignment of emissions to areas with refineries and an under-assignment to areas without refineries. As noted in the DEIS, this is a limitation of the GREET model, which does not provide a breakdown of fuel-refining emissions versus transportation, storage, and *distribution emissions. NHTSA has not been able to identify any data that would allow a further breakdown of upstream toxic emissions by source.*

Page 3-23: For the DEIS, NHTSA modeled upstream emissions of air toxics using emissions factors from Winebrake et al. (2000). This is the same source used for the 2000 air toxics version of GREET. NHTSA coordinated with EPA to update the air toxic upstream emissions factors for upstream processes. However, EPA stated that it would not be able to supply updated factors. EPA recommended that NHTSA continue to use the air toxic upstream emissions factors it used in the DEIS and that NHTSA revise the text in Sections 3.3.2.1.3 and 3.3.2.1.5 of the FEIS to explain the EPA recommendation. NHTSA has revised the FEIS accordingly. The statuses of some of the specific model limitations the commenter mentioned are as noted below and in the FEIS:

- *Ethanol production not included: This model limitation still exists.*
- *Transport vehicles: These emissions factors have been updated. See also the previous comment response in this section (10.3.2.2).*
- *Evaporative benzene emissions: This model limitation still exists.*
- *Refinery process emissions factors: These emissions factors have been updated. See also the previous comment response in this section (10.3.2.2).*
- *Updating of air toxic upstream emissions factors for upstream processes: As noted above, NHTSA coordinated with EPA to update the air toxic upstream emissions factors for upstream processes. However, EPA stated that it would not be able to supply updated factors. EPA recommended that the NHTSA continue to use the air toxic upstream emissions factors it used in the DEIS and that NHTSA revise the text in Sections 3.3.2.1.3 and 3.3.2.1.5 of the FEIS to explain the EPA recommendation. NHTSA has revised the FEIS accordingly.*

Page 3-25, page 3-28, Tables 3.3-3 and 3.3-5: NHTSA has updated the text and emissions tables in Section 3.3.

10.3.2.3 Consequences

Comment

Comment Number: 0588-12
Organization: New York State Department of Transportation
Commenter: Stanley Gee

Figures 3.3-3, 3.3-4, and 3.3-5 should show the effects of the proposed alternatives on light duty cars and light duty trucks separately. This would help to distinguish the differential effect that the various alternatives will have on the various components of the nation’s light duty fleet.

Response

NHTSA has added a table to Section 3.2.2 to show the effects of the alternatives on cars and light-duty trucks separately.

Comment

Comment Number: 0595-19
Organization: Environmental Protection Agency
Commenter: Susan Bromm

Chapter 3, pg 3-27, Figure 3.3-2:

This figure, and others like it, suffers from a scale mismatch related to the tons associated with CO versus each of the other criteria pollutants. The different reductions between alternatives for PM, NO_x, SO_x, and VOCs are not minor. However, the scale of the table gives this misimpression. EPA recommends that CO be decoupled from this table, shown separately, and the scale of the existing table be revised to more accurately show differences in the alternatives for the other criteria pollutants.

Response

NHTSA has revised the relevant figures in Section 3.3.2.3 to more clearly show the differences among the pollutants.

10.3.2.4 Health

Comment

Comment Number: 0595-14
Organization: Environmental Protection Agency
Commenter: Susan Bromm

Chapter 3, pg. 3-13, line 34:

EPA recommends the following sentence be added to the beginning of the paragraph, to clarify that a formal health impact analysis was not done:

"Though we did not conduct a formal analysis of health impacts, the alternatives considered in this EIS will contribute to reductions in criteria pollutants that will improve public health and welfare."

Response

NHTSA acknowledges the request and has added this sentence to Section 3.3.1.2.

Comment

Comment Number: 0595-25
Organization: Environmental Protection Agency
Commenter: Susan Bromm

Chapter 1, pg. 1-7, Lines 20-28:

It does not appear that NHTSA undertook a complete health impacts analysis in its analysis of alternatives. Instead, the Volpe model substitutes $/ton values which reflect a measure of the monetized health related benefits associated with criteria pollutant emission reductions. The $/ton numbers omit a number of unquantified health and environmental effects, and are therefore an underestimate of total benefits. A complete health and environmental impacts analysis would begin with full-scale photochemical air quality modeling to demonstrate the changes in ambient air pollution exposure related to the emission changes associated with each alternative scenario. These ambient concentrations would then be fed through a health impacts model (EPA's Environmental Benefits and Mapping Analysis Program – BenMAP) to characterize population exposure and the change in health response associated with various health impact functions derived from the epidemiological literature.

Response

NHTSA has expanded the discussion of dollars-per-ton values to better explain how the emissions changes associated with the alternatives would produce these economic and health outcomes. NHTSA has added data to show, at a screening level, the health outcomes implied by the dollars-per-ton values. See Section 3.3.2.4.2.

Comment

Comment Number: 0596-10
Organization: Environmental Defense Fund
Commenter: Martha Roberts

NHTSA acted in an arbitrary and capricious manner by justifying attribute-based standards as a means to "eliminate the incentive for manufacturers to respond to CAFE standards in ways harmful to safety," while simultaneously ignoring the health consequences presented by the lower fuel efficiency permitted in larger vehicles. [Footnote: See original comment document.]

NHTSA purports to consider human health in developing CAFE standards through the use of attribute-based standards and rules in the VOLPE model that limit vehicle downweighting as a fuel efficiency technology. However this same health safety concern is not evident in the choice of fuel efficiency standards. Particularly egregious are the lower fuel efficiencies permitted to larger vehicles, which increase the harm to human health through increased emissions of air pollutants.

NHTSA refers to several reports on safety and vehicle weight reduction and quotes the National Academy of Science's finding that in 1993 between 1,300 and 2,600 traffic accident fatalities occurred as a result of earlier vehicle downsizing and weight reductions. [Footnote: See original comment document.] This is less than the estimated number of deaths attributable to air pollution from a less stringent CAFE standard, as compared to a more stringent one [see Table 1 in original comment document].

We request that NHTSA give the same attention to protecting human health from air pollution as it does to protecting human health in its analysis of crashworthiness. A more stringent CAFE standard will better balance the benefits of health protection with the other statutory considerations and better align with NHTSA's attribute-based safety justifications.

Response

The air quality analysis compares the health outcomes of the alternatives, as noted in the previous comment response in this section (10.3.2.4). These can be compared with the safety analysis in Section 3.5.4.

More specifically, it is important to note the context in which the action will occur, because the commenter appears to misconstrue the legal requirements under EPCA, as amended by EISA. NHTSA does not have the discretion to decide whether to adopt an attribute-based standard. Congress, in the *language of EPCA, required NHTSA to adopt an attribute-based standard. The National Academy of Sciences (NAS) also recommended an attribute-based standard. Different fuel economy targets for different sized vehicles are a necessary consequence of an attribute-based standard. In fact, different fuel economy targets by vehicle attributes are the reason why the NAS recommended, and Congress directed, NHTSA to address perceived disadvantages of the existing fuel-economy standards.*

One commenter stated that, as a policy choice, a more stringent CAFE standard represents a better balance between the health outcomes (mortality and illnesses) avoided by emissions reductions and the health outcomes (fatalities and injuries) avoided by improved crashworthiness. The preeminent goal of EPCA is energy conservation. While greater human health benefits from the more stringent alternatives would certainly be desirable (as would greater fuel savings or GHG reductions), NHTSA must act within the requirements of economic practicability and technological feasibility established under EPCA.

Comment Number: 0600-5
Organization: Centers for Disease Control and Prevention
Commenter: Sarah Heaton

Transportation-related emissions contribute to climate change. CAFE standards can promote the use of alternative technologies in the U.S. and abroad that reduce harmful emissions and, in turn, reduce contributors to climate change and improves human health outcomes. Although some health outcomes of climate change are difficult to predict, others are supported by considerable evidence. Health impacts affected by increasing or reducing contributors to climate change are appropriate for analysis of the human environment pursuant to NEPA.

Health outcomes from climate change, for which quantitative or qualitative impact analysis is possible, should be included in predictive modeling.

Automobile contributions to criteria air pollutants are affected by CAFE standards and such emissions directly affect human health outcomes. Asthma, bronchitis, chronic obstructive pulmonary disease, and cardiovascular disease are some of the most common health outcomes triggered or exacerbated by air pollutants from motor vehicles. Reducing ozone forming emissions, NOx, and hydrocarbons can improve human health outcomes and reduce medical care costs. The DEIS fails to discern among alternatives regarding the health impacts from emissions/air pollutants. For adequate analysis of impacts to the human environment pursuant of NEPA:

Analysis of the potential health effects from fleet emissions, both acute and chronic, is critical to include in the analysis of alternatives pursuant to NEPA.

Adequate cost/benefit analysis of alternatives should include health costs associated with the acute and chronic effects from auto emissions at each level in the range of alternatives to show both current associated costs and potential savings from reduced emissions.

Comment Number: 0596-6
Organization: Environmental Defense Fund
Commenter: Martha Roberts

NHTSA fails to comply with the NEPA regulations requiring agencies to “present the environmental impacts of the proposal and the alternatives in comparative form, thus sharply defining the issues and providing a clear basis for choice among options by the decisionmaker and the public" (CEQ 40 CFR 1502.14) in this EIS. In particular, the EIS fails to disclose the likely adverse health effects of conventional air pollutants associated with each alternative, fails to compare alternatives based on their impact on human health, and fails to identify how each alternative considered will eliminate or minimize these health effects. The EIS completely ignores the responsibility under NEPA to provide useful information to the decision maker regarding the degree to which each alternative will protect the public from the adverse health effects of air pollution from the transportation fuel cycle.

Council for Environmental Quality (CEQ) regulations require that an EIS assess both the direct and indirect effects of proposed actions and their significance (CEQ 40 CFR 1502.16 (a) and (b)), which include those effects related to human health (CEQ 40 CFR 1508.8) and requires that an EIS consider the "degree to which the proposed action affects public health or safety." (40 CFR 1508.27(b)(2)). Because the proposed alternatives will each significantly change human exposure to transportation fuel cycle emissions for the American public, and the adverse health effects resulting therefrom, a comparison of alternatives based on public health impacts is required. Under the CEQ regulations and settled case law, NHTSA cannot exclude these effects, which are obviously related to the proposed standards, from its EIS analysis.

The proposed CAFE alternatives result in varying levels of future air pollutant emissions that will differentially affect human health. NHTSA asserts that "assessing emissions is a valid approach to assessing air quality impacts because emissions, concentrations, and health effects are connected. Lower emissions should result in lower ambient concentrations of pollutants on an overall average basis, which should lead to decreased health effects of those pollutants." [Footnote: See original comment document.] However, the magnitude of this effect requires quantification, even if that quantification is subject to some uncertainty. The rote description of the various air pollutants and their related health impacts provided by the EIS does not satisfy NEPA. In the words of the Ninth Circuit court, "[g]eneral statements about "possible" effects and "some risk" do not constitute a "hard look" absent a justification regarding why more definitive information could not be provided." [Footnote: See original comment document.]

The EIS provides the relative future reduction of criteria air pollutants and hazardous air pollutants (HAPs) across the range of proposed CAFE alternatives. Unlike recent EPA regulatory impact analyses (RIAs) [Footnote: See original comment document.] however, this EIS fails to specify the relative human health impacts resulting from each emissions scenario.

To demonstrate that such a linkage is possible and to suggest the relative magnitude of the health effects of the various CAFE alternatives, we have used a simple methodology to estimate multiple health outcomes. This method quantifies the relationship between the amount of emitted pollutant and human health effects. Our approach, although slightly different methodologically from that used by the EPA, relies upon much of the same scientific literature and appears to provide similar results. We use the predicted future tonnage of conventional air pollutants in the EIS in association with the intake fraction, a unitless measure of the percent of an emitted pollutant that is inhaled or ingested by the population at large. [Footnote: See original comment document.] These two variables, in conjunction with empiric measures of exposure-response relationships, allow us to characterize the health effects related to different quantities of pollutant emissions. Basically the amount of emitted pollutant is multiplied by the intake fraction (calculated for the U.S. using spatial statistics to account for the locations and densities of emissions and people). We then multiply this number by a series of different exposure-response coefficients for different health outcomes, such as lung cancer, cardiovascular mortality, etc. The final product is the number of attributable health events for each pollutant over a year.

We found striking and troubling differences in the health impacts of the proposed CAFE alternatives, measured in thousands of avoided premature deaths. For example, in comparing the “optimized” (NHTSA’ s preferred standard) alternative with the more stringent “total costs equals total benefits” (“costs = benefits”) alternative, over 1,400 excess infant deaths per year result under the “optimized” alternative by 2020. In addition, the “optimized” alternative leads to more than 2,800 additional adult premature deaths, 8,800 children’s emergency room visits for asthma, and 640,000 lost work days yearly by 2020. See Table 1 [See original comment document for Table 1.] for more details on the health impacts of the various proposed CAFE alternatives.

Our analysis examined the health effects of only two pollutants, particulate matter ($PM_{2.5}$) and nitrogen dioxide (NO_x), of the more than ninety harmful air pollutants emitted by light vehicles. [Footnote: See original comment document.] Thus we significantly underestimate the true health protection of higher fuel efficiency.

The EIS, by omitting quantified health benefits, disregards one of its core purposes, namely, to “inform decisionmakers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment” (CEQ 40 CFR Sec. 1502.1). NHTSA must revise the EIS to include calculations of meaningful health outcomes, such that policy makers and the public more fully understand the implications of the proposed CAFE alternatives.

Response

The FEIS approach of relating relative reductions in emissions to relative reductions in health effects supports the primary NEPA purposes of informing the selection of an alternative, informing the decisionmaker of potential effects to human health and the environment, and ensuring public disclosure of information. Given these purposes, one objective of NEPA is generally to disclose adverse health outcomes. However, the outcomes of the CAFE rule will generally reduce emissions and be beneficial to human health, even though not all alternatives reduce emissions for all input scenarios and analysis years. The FEIS follows NEPA guidance by analyzing all impacts, even when the effects would be positive.

One commenter compares this EIS to EPA’s RIAs for its air quality rulemakings. A rulemaking in which the primary purpose is to reduce health risks, such as those promulgated by EPA, might need to be more explicit than this EIS about the health impacts that would be avoided through implementation of a proposed action. However, the CAFE rule is substantially different from EPA rules. Most significantly, EPA rules are designed for the express purpose of improving health through pollution reduction, as mandated by the Clean Air Act and other statutes. In contrast, the purpose of CAFE standards, as mandated by EPCA, is to reduce fuel use.

EPA, in the technical support documents to its "Advance Notice of Proposed Rulemaking: Regulating Greenhouse Gas Emissions under the Clean Air Act" of July 2008 (EPA 2008g), used a similar approach to NHTSA's that also examined the benefits, rather than the harm, of GHG reductions.

To provide more detailed information on the projected health benefits by alternative, NHTSA has expanded the discussion of air quality and health effects with more quantitative information on the relative impacts of the alternatives. Sections 3.3.2.4.2 and 4.3.3.2.3 of the FEIS provide estimates of the number of cases avoided for various health outcomes and the dollar value of avoided costs associated with the emissions reductions under each alternative.

NHTSA disagrees with the Environmental Defense Fund’s (EDF’s) characterization that the Optimized Alternative results in “over 1400 excess infant deaths” and “leads to more than 2800 *additional adult premature deaths." None of the alternatives would cause premature mortality. All of the alternatives are estimated to reduce adverse health outcomes to differing degrees; from this result it cannot be concluded that all alternatives except the most stringent would cause "excess," "additional," or "premature" outcomes. All of the action alternatives, including the Optimized Alternative, would reduce emissions of NO_x, $PM_{2.5}$, SO_x, VOC, DPM, benzene, and 1,3-butadiene and thus should lead to reduced mortality.*

Comment

Comment Number: TRANS-17-1
Organization: BG Automotive Group
Commenter: Barry Bernsten

What I did not read in the 414 pages of the environmental impact statement as it clearly relates to air quality, was the direct associated cost with the 1.5 million emergency room visits for asthma patients, or the $14 billion in health care costs related just to asthma related illnesses.

The report also did not include the direct costs associated with emphysema and/or chronic bronchitis due to CO_2 emissions or greenhouse cases. Why didn't the environmental impact statement consider the direct health costs associated with their study, and the quality of life costs associated with such an important report?

Response

NHTSA has expanded the discussion of air quality and health effects to provide more quantitative information on the relative impacts of the alternatives. See Sections 3.3.2.3.2 and 4.3.3.2.3.

Comment

Comment Number: TRANS-32-1
Organization: Environmental Defense Fund
Commenter: James Keck

EDF, while supporting the inclusion of climate change health impacts within the EIS is deeply concerned by the assertion that the agency and its consultants were unable to determine the magnitude of these impacts across the proposed CAFE alternatives, not only on the basis of climate change, but also regarding conventional pollutant health impacts.

Response

Two federal agencies, EPA and Centers for Disease Control and Prevention (CDC), commented on the human health discussions in the DEIS. EPA noted that NHTSA did not perform a complete health analysis. Rather than calling for additional analyses, EPA suggested that NHTSA insert text that would explain the level of analysis performed. EPA stated that a "complete health and environmental impacts analysis would begin with a full scale photochemical air quality modeling to demonstrate the changes in ambient air pollution exposure… These ambient concentrations would then be fed through a health impacts model… to characterize population exposure and the change in health response…." EPA provides text describing what NHTSA did and did not perform. By contrast, CDC called for more extensive modeling analysis, recommending that NHTSA include economic analysis of health costs and commenting that mitigation analysis is necessary. CDC draws on the wedge analysis described by Pacala and Socolow in Science magazine in 2004. CDC also had specific recommendations regarding *human health impacts associated with changes in fleet emissions, fuel consumption, and fleet design. Other parts of this chapter address these specific suggestions.*

Sections 3.5.4, 3.3.1.2, 3.3.1.3, and 4.5.8 discuss impacts to human health. NHTSA has provided a thorough description of how emissions can affect human health, specific assessments of the changes in emissions due to the standards, and discussions of impacts to human health from direct, indirect, and cumulative impacts perspectives based on information from the IPCC and the U.S. Climate Change Science Program (USCCSP). NHTSA has enhanced the information provided in the FEIS by including data on the potential health outcomes and costs reduced under each of the alternatives. NHTSA's reasoning is explained further below.

NHTSA appreciates and adopts the language EPA suggested to clarify the level of health analysis performed. NHTSA also notes EPA's description of the extensive photochemical, exposure, and health analysis that would be required to conduct a full-scale health-impacts analysis. NHTSA believes that adopting the text clarifications EPA suggested is a better approach than attempting to conduct more extensive health-impacts modeling, for two main reasons. First, the estimated health impacts resulting from the CAFE standards are beneficial. Because the alternatives would reduce GHGs and health costs (see Sections 3.4, 3.5, 4.4, and 4.5), the damage to human health is estimated to be similarly reduced. Although this does not relieve NHTSA from explaining the potential impacts to human health, it reduces the need for enhanced analytical rigor when compared to a case in which human health might be negatively affected.

Although one might argue that enhanced analysis might still be necessary even if the impacts were beneficial, NHTSA would note that improving human health is not the purpose of the proposed rulemaking. If it were, greater credence could be given to the need for enhanced analysis. The statutory purpose of the proposed rulemaking is to save energy, which according to the analysis in the DEIS and this FEIS, is expected to improve human health.

Second, the differences in emissions (GHGs, criteria pollutants, and air toxics) and in health costs avoided among the alternatives provide ample information for the decisionmaker, as required under NEPA. It is reasonable to anticipate that human health impacts will mirror these indicators. The information to be gained through the very extensive process of health modeling would not add substantial new information because the differences in estimated climate effects (temperature, precipitation, and sea-level rise) are small; therefore, changes in the health impacts related to these will also be small. Further, the differences among the alternatives will be smaller still, due to the global nature of the climate problem. Similarly, the screening-level analysis of avoided adverse human health outcomes and avoided health costs of criteria pollutants among the alternatives provides ample information for the decisinomaker, as required under NEPA.

To address CDC's request for additional economic/health-impacts analysis, NHTSA has provided more information in the FEIS regarding the relative health effects of criteria air pollutant emissions associated with the alternatives. Specifically, NHTSA has expanded the discussion in Sections 3.3.2.4.2 and 4.3.3.2.3 to include estimates of the number of cases avoided for various health outcomes and the dollar value of avoided costs associated with the emissions reductions with each alternative. This analysis is limited to the criteria air pollutants, because health damage estimates are not available for MSATs.

In suggesting further modeling, CDC cites the wedge analysis by Pacala and Socolow and might, therefore, misconstrue the action NHTSA is taking. NHTSA's action is limited to the CAFE rulemaking. The proposed rulemaking would result in substantial reductions in GHG emissions from passenger cars and light trucks in the United States, which when considered in a global context, would result in small *changes in temperature, precipitation, and sea-level rise. The proposed rulemaking also would result in substantial reductions in national emissions of NO_x, $PM_{2.5}$, SO_x, VOC, DPM, benzene, and 1,3-butadiene from passenger cars and light trucks in the United States, which would lead to incremental reductions in adverse health outcomes and costs. Under NEPA, the proposed rulemaking is the action that must be evaluated for environmental impacts. The FEIS does not, and should not in NHTSA's opinion, account for other emissions-reduction strategies beyond those reasonably foreseeable, as NEPA requires. Because the United States has not established in law or regulation other emissions-reduction strategies (except the MY 2016-2020 CAFE targets specified in EISA), including presumed improvements in energy efficiency, would be speculative. Accordingly, NHTSA continues to believe that the appropriate context for analysis of human health impacts is limited to the reduction in emissions resulting from the alternatives specified in the proposed rule. To provide more detailed information on the projected health benefits by alternative in the FEIS, NHTSA has expanded the discussion of air quality and health effects of criteria and toxic pollutants to provide more quantitative information on the relative impacts of the alternatives. Section 3.3.2.4.2 of the FEIS provides estimates of the number of cases avoided for various health outcomes and the dollar value of avoided costs associated with the emissions reductions with each alternative.*

Comment

Comment Number: TRANS-32-6
Organization: Environmental Defense Fund
Commenter: James Keck

The EIS notes that health costs are included within the Volpe model, used to select optimized alternative, but it fails to include estimates of adverse health events in its statement. And while the EIS provides the future relative reductions in tons of air pollutants across the different CAFE alternatives, it does not link these air pollutant reductions to health in a transparent and meaningful way.

To demonstrate that such a linkage is possible, we used a simple methodology to estimate the changes in meaningful health outcomes associated with a different CAFE alternatives. Although I do not have the time to relay all of the specific details of our findings, the health protection resulting from, for example, the pollutant reductions in the cost equals benefits alternative versus the optimized CAFE alternative is measured in thousands of avoided deaths, and thousands of avoided asthma visits to the emergency department per year by the year 2020.

Response

NHTSA has expanded the discussion of air quality and health effects to provide more quantitative information on the relative impacts of the alternatives. See Section 3.3.2.4.2.

10.3.3 Climate

Comment

Comment Number: 0530-2
Organization: Individual
Commenter: Dale Olson

Over 32,000 scientists have signed the "Oregon petition" stating they see no convincing scientific evidence that humans are causing catastrophic climate change. They have been joined by the American Physical Society, which recently announced that it was reassessing its prior position - that evidence for global warming was "incontrovertible" - because many of its 50,000 physicist members disagree strongly with climate chaos claims.

Response

The American Physical Society (APS) released a statement clarifying that the contrary viewpoint espoused by some of its members was not the official position of the APS. The APS states in a position adopted on November 18, 2007 that "The evidence is incontrovertible: Global warming is occurring." National Policy 07.1 Climate Change, available at http://www.aps.org/policy/statements/07_1.cfm. NHTSA uses the best available science from IPCC and CCSP in its analyses. Both of these groups, along with most scientists around the world, agree that human-induced climate change is occurring.

Comments

Comment Number: 0572-26
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

One prime example of inadequate context and information is the analysis of abrupt climate change, or tipping points. The CEQ regulations require that an agency "describe the consequences of a remote, but potentially severe impact" based on credible scientific information. 50 Fed. Reg. 32234, 32237 (August 9, 1985). The DEIS acknowledges that the possibility of abrupt climate change exists, yet by asserting uncertainty downplays the significance of tipping points. This approach is untenable. While no one may be able to predict with certainty on exactly which date a threshold for abrupt climate change may be reached, there is ample evidence that unchecked greenhouse emissions will result in abrupt climate change. In fact, various studies have attempted to quantify when such a threshold may be reached. The most recent estimate by Hansen and colleagues is that prolonged time spent over 350 ppm CO_2 will result in catastrophic impacts. (Although the climate literature often refers to "dangerous" levels of climate change to denote CO_2 concentrations above which climate impacts will be severe and irreversible, we use the term "catastrophic" here because current CO_2 levels have already surpassed the "dangerous" level of 350 ppm.) Previous estimates considered 450 ppm the threshold for catastrophic climate change.

Given the certainty that abrupt climate change will occur above some level of atmospheric concentration, the alternatives must be analyzed in the context of avoiding catastrophic climate change.

The DEIS does not adequately address climate tipping points.

Among the many consequences of climate change, "tipping points" carry the greatest threat to wildlife, human welfare, and economic security. As such, it is of paramount importance that any federal action be executed in a manner that reduces the possibility of abrupt climate change.

The Volpe model is the sole decision-making tool used to balance the factors set out in the EPCA. It does not capture the costs of abrupt climate change or tipping points. One of the factors that NHTSA considers under EPCA when setting the fuel standards is "the need of the United States to conserve energy." Environmental implications of the need for large quantities of petroleum are included in this factor. One of the environmental effects of continued heavy petroleum consumption is the possibility of passing over "tipping point" thresholds, or catastrophic climate change.

Because this is an acknowledged possibility, it must be included in the NEPA analysis and the balancing of the EPCA factors. The DEIS concludes that the science surrounding tipping points is too uncertain to be included in the analysis. This is simply not true. It is well-accepted that there will be tipping points.

(Meehl et al. at 775, 2007) A recent analysis of “tipping elements” indicates that contrary to the IPCC’s conservative projections, there is a strong chance that tipping points will be crossed within this century (Lenton et al. 2008). This study also indicates that it may be possible to identify thresholds for tipping points for the purposes of policy making.

Furthermore, a recent study by Weitzman, an economics professor at Harvard, indicates that while traditional cost-benefit analysis can not properly capture the costs of climate change, including tipping points, a different analysis is more likely to capture the costs (Weitzman 2007).

The economic impacts of climate change are astounding. The much-respected Stern Review, published in 2007, estimates that the costs of climate change will range from 5% to 20% of GDP. (Stern 2007). In contrast, the Stern Review estimated that rapid action to address climate change would only cost approximately 1% of GDP. [Footnote: See original comment document.] In 2007, this would have corresponded to approximately $138 billion. [Footnote: See original comment document.] In contrast, the cost of inaction—abrupt climate change—has been estimated at over $400 billion. [Footnote: See original comment document.] The message is clear: the U.S. can not afford to gamble with abrupt climate change.

Under all scenarios considered in the DEIS the atmospheric CO_2 concentrations would reach 550 ppm or greater—the “optimized” alternative would reach over 700 ppm. This is well above the threshold for abrupt and catastrophic climate change. As a result, no alternatives adequately address the need for deep reductions in CO_2 emissions.

The DEIS erroneously dismisses the potential for tipping points as an impact that will not occur this century and thus does not require consideration. The basis for this conclusory statement that abrupt climate change will not occur this century is a statement in the IPCC Fourth Assessment Report that ”[a]brupt climate changes … are not considered likely to occur in the 21st century, *based on currently available model results*.” See DEIS at 3-53 (emphasis added; citing Meehl et al. 2007). Yet, it is well accepted that climate models can not capture the dynamical processes that lead to climate instabilities and rapid shifts such as occur during abrupt climate change. See, e.g., DEIS at 3-52.

Model predictions consistently underestimate observed climate change, and thus very likely also underestimate when tipping points will occur. For a discussion and examples, see Hansen et al., *Target CO_2* at page 10 (2008). There are numerous examples of accelerated changes occurring well in advance of model predictions. One is the rapid rate of sea ice loss in the Arctic. The summer sea ice extent in 2007 shattered all records, dropping below the level that most models predicted would not occur until 2050. [See original comment document for figures.]

More recent models of Arctic sea ice predict that the Arctic could be sea-ice free by the summer of 2013. In a recent conference presentation, Professor Maslowski from the Naval Postgraduate School showed if current trends continue, the Arctic will be sea-ice free by 2013. (Maslowski et al. 2008) The summer sea ice predictions for 2008 suggest that the same precipitous decline may occur again [Footnote: See original comment document.], with some scientists suggesting a 50:50 chance that the North Pole will be ice-free this summer. [Footnote: See original comment document.] Arctic sea ice is important both because of the albedo feedback effect and because sea ice melt leads to a warmer Arctic Ocean, which in turn accelerates the melt rate of the Greenland ice sheets.

The best basis for determining tipping points may be the use of paleoclimate data. Based on such data, Hansen and colleagues have estimated that remaining at CO_2 concentrations above 350 for a prolonged period of time is likely to invoke tipping points (Hansen et al. 2008). Paleoclimate data also indicate that in the past, at temperatures expected to be reached by 2100, Greenland and Antarctica contributed several meters to sea level. (Overpeck et al. 2006) The rate of rise at this temperature was approximately 1.6 m/century. (Rohling et al. 2008) Thus, the current CO_2 level of 385 ppm is not only “dangerous,” but catastrophic and could lead to tipping points this century. No models, including those used by the IPCC, can capture the dynamic response of ice sheets or adequately predict current observations of sea level rise. (DEIS at 3-75; Rignot 2008)

Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

In addition, the Ninth Circuit recently observed, in Center for *Biological Diversity v. National Highway Traffic Safety Administration*, that incremental increases in CO_2 can lead to abrupt, catastrophic, and irreversible changes, and that “even a small increase in greenhouse gases could cause abrupt and severe climate changes” (U.S.C. § 32902(a),(f)). [Footnote: See original comment document.] As such, NHTSA must consider not just the significant environmental, social, and economic benefit to achieving the maximum technologically feasible fuel economy and, therefore, greenhouse gas emissions reductions, but also the high premium associated with achieving dramatic reductions in the near-term.

Comment Number: 0585-8
Organization: Attorneys General of the States of California, Massachusetts, New Jersey, New Mexico, New York, and Oregon, Secretary of the Commonwealth of Pennsylvania Department of Environmental Protection, and New York City Corporation Counsel
Commenter: Edmund Brown Jr., Joseph Powers, Martha Coakley, Michael Cardozo, Anne Milgram, Gary King, Andrew Cuomo, Hardy Myers

The DEIS fails to present the data in a meaningful context. The DEIS fails to consider the scientific consensus that CO_2 concentrations must be kept below the level of “dangerous anthropogenic interference”

While the DEIS provides a significant amount of raw data, the data are meaningless unless they are put into context. For example, simply reporting that the new CAFE rule puts us on a trajectory to reaching CO_2 levels of over 700 ppm and an increase in temperature of over 2 degrees Celsius by 2100 (DEIS at 4-3 1), is meaningless to the uninitiated because it does not provide the context related to the “tipping point” beyond which devastating and irreversible climate change impacts may occur.

While the DEIS mentions the concept of a climate “tipping point” and the fact that some climate scientists believe that a CO_2 level exceeding about 450 ppm is dangerous (DEIS at 3-52 to 3-53), it then dismisses these concepts as “still a matter of scientific investigation” (DEIS at 1-10), and claims that “the state of the science does not allow for a characterization of how the CAFE alternatives influence these risks, other than to say that the greater the emission reductions, the lower the risk of abrupt climate change.” DEIS at 3-53 to 3-54, 4-26.

This perfunctory discussion is unacceptable. To put the raw data into a meaningful context, the DEIS should emphasize the scientific consensus that we must lower our GHG emissions significantly in order to keep CO_2 concentrations in the atmosphere below a threshold that represents “dangerous anthropogenic interference” (“DAT”). In the words of the Ninth Circuit, there is “compelling scientific evidence concerning ‘positive feedback mechanisms’ in the atmosphere” that could lead to abrupt and non-linear changes. Center for Biological Diversity, 508 F.3d at p. 554. While the precise level for DAT is not known, scientists generally agree that the threshold is below 550 ppm CO_2. [Footnote: See original comment document.] At higher levels it is likely we will have reached an irrevocable “tipping point” and the Greenland ice sheet and part of the west Antarctic ice sheet will ultimately melt, causing a 5 to 10 meter rise in global sea level, which will cause flooding of all major coastal cities, and ensure global cataclysm. Further, it is plausible that DAT will be reached even at CO_2 concentrations of 450 ppm or substantially lower. [Footnote: See original comment document.] The risk of environmental cataclysm, even if uncertain, is so enormous, that it cannot simply be ignored, as NHTSA does.

At the very least, the DEIS must inform the agency and the public that scientists agree that there is an area of dangerous anthropogenic interference in the range of 500 ± 50 ppm $C0_2$, or possibly lower, that must be avoided. This information must be incorporated into and direct the analysis. Without such information, it is clear that NHTSA has, in fact, not considered the issues in a meaningful way.

Comment Number: 0595-6
Organization: Environmental Protection Agency
Commenter: Susan Bromm

EPA recommends that the DEIS discussion of climate change tipping points be expanded somewhat in the FEIS to include a brief discussion of the impacts associated with a given tipping element, and to include a reference to additional tipping elements identified by the scientific community (see Lenton, T. M., Held, H., Kriegler, B., Hall, J. W., Lucht, W., Rahmstorf, S. and Schelinhuber, H. J. (2008). Tipping elements in the Earths climate system. Proceedings of the National Academy of Sciences, Online Early Edition. February 4, 2008), including:

- Increase in the El Nino Southern Oscillation
- Collapse of the Indian summer monsoon
- Greening of the Sahara/Sahel and disruption of the West African monsoon
- Dieback of the Amazon rainforest
- Dieback of the Boreal Forest

Response

Commenters asked NHTSA to consider the issue of tipping points in the climate system in more detail. NHTSA has expanded its consideration of the issue of tipping points to include new research, as suggested by commenters, and expanded the discussion from the IPCC and CCSP literature. See Section 3.4.3.2.4. NHTSA also has included paleoclimatic research, as suggested by commenters, which supports the hypothesis that abrupt and severe climate change has occurred in the past, and that these changes could occur in multiple climate systems or other climate-related systems on the planet that affect global climate patterns. While the expanded research NHTSA analyzed in response to comments appears to confirm that there is general agreement that there are thresholds in the climate system that might produce severe and abrupt climate changes and impacts, there is still substantial uncertainty surrounding the existence of a singular tipping point (whether that point is 450 ppm CO_2 concentration or a 2 ºC temperature increase). There is evidence of multiple tipping points within various global systems, supported in scientific observations, peer-reviewed scientific literature, and paleoclimatic data. These points might occur when CO_2 concentrations are lower than 450 ppm and would have varying direct and indirect impacts. However, there is also uncertainty about exactly what levels of CO_2 emissions or temperatures might trigger these thresholds.

Commenters also requested that NHTSA examine the alternatives in relation to reaching tipping points triggered by CO_2 emissions. While NHTSA considered the potential to explore this suggestion in greater detail, we believe that such an analysis is not meaningful. Indeed, due to the uncertainty about what the impacts of this action are in delaying or mitigating the triggering of tipping points in any quantitative manner, it is impossible for NHTSA to relate the reductions in CO_2 emissions, sea-level rise, precipitation changes, and temperatures to tipping-point thresholds or to what extent the different *alternatives would affect tipping points. This action alone, even as analyzed for the most stringent alternative, does not produce enough of a CO_2 emissions reduction to prevent abrupt and severe climate change. The issue of abrupt and severe climate change tipping points must be addressed with many more CO_2-reduction initiatives and will require a global effort to address. Under NEPA and applicable law, due to the incomplete and unavailable nature of the information surrounding this issue, the only non-speculative conclusion NHTSA can reach is that the reduction in CO_2 emissions expected under this rulemaking will lower the risk of abrupt climate change.*

10.3.3.1 Methodology

Comments

Comment Number: 0585-10
Organization: Attorneys General of the States of California, Massachusetts, New Jersey, New Mexico, New York, and Oregon, Secretary of the Commonwealth of Pennsylvania Department of Environmental Protection, and New York City Corporation Counsel
Commenter: Edmund Brown Jr., Joseph Powers, Martha Coakley, Michael Cardozo, Anne Milgram, Gary King, Andrew Cuomo, Hardy Myers

In making this determination, the DEIS could also make use of the concept of “stabilization wedges,” first advanced by Pacala and Socolow. [Footnote: See original comment document.] Pacala and Socolow envisioned the 50-year reductions scenario as a triangle, with the sides of the stabilization triangle delineated by a flat emissions trajectory of 7 gigatons carbon per year (“GtC/year”) by 2054, with a decline to zero emissions by sometime after 2100, and a “business as usual” scenario represented by a straight-line ramp rising to 14 GtC/year in 2054. (Footnote: See original comment document.] (We note, however, that the analysis was performed in 2004. Four years later, the amount of emissions reductions per wedge will have increased, so that the 7 GtC/year is likely too low an estimate. They then divided the stabilization triangle into seven equal wedges representing reductions in GHG emissions. Filling all seven wedges results in reducing GHG emissions sufficiently to stabilize CO_2 concentrations at 500 ppm. [Footnote: See original comment document.] In particular, they note that we will achieve one wedge of the stabilization triangle if cars in 2054 averaged 60 miles per gallon globally. [Footnote: See original comment document.]

The wedge analysis was applied by the EPA in discussing GHG emissions from the U.S. transportation sector. The EPA calculated that nine transportation wedges, each representing a reduction of 5,000 million metric tons of CO_2 equivalents (“MMTCO2e”) between now and 2050 would be enough to flatten emissions in the transportation sector. Of the nine wedges, about half (4.3) would be enough to flatten emissions from passenger vehicles. EPA Transportation Wedge Analysis at 2. The EPA analysis notes that the reductions in emissions from passenger vehicles will come from vehicle technology, alternative fuels, and travel demand reduction, acting in concert. The document then presents various vehicle technologies and the “reduction potential” for the technology in terms of wedges. [Footnote: See original comment document.]

NHTSA could, consistent with the EPA analysis, compare the GHG emissions from the proposed CAFE alternatives with the 4.3 wedges of reductions needed from the passenger car sector to reach emission stabilization by 2054 and begin the necessary decline in emissions. (Additional reductions may be created by other actions, such as those that reduce travel demand or VMT. However, these further reductions will be necessary to lower GHG emissions even further in order to reduce CO_2 concentrations below 500 ppm.) [Footnote: See original comment document.] This will enable the Agency to determine whether the proposed alternative will slow emissions growth sufficiently from the passenger car and light truck sector to flatten emissions as anticipated by the EPA analysis. If it will not, NHTSA must reassess the alternatives.

Organization: Centers for Disease Control and Prevention
Commenter: Sarah Heaton, Andrew Dannenberg

CAFE standards' impact on climate change deserves special attention. In the magazine *Science* (2004), S. Pacala and R. Socolow articulate the concept of an orchestrated approach to solving climate change with existing technologies, policy change, and behavioral changes. Each component in such an approach is referred to as a *Stabilization Wedge* (Pacala and Socolow, "Stabilization Wedges: Solving the Climate Problem for the next 50 Years with Current Technologies" *Science* 2004 Aug 13;305: 968-972). CAFE standards that increase fuel efficiency is a critical and necessary component in the wedge approach and ought to be assessed in this context.

Response

NHTSA recognizes that several approaches have been put forth for developing comprehensive, multi-sector strategies to reduce GHG emissions. The stabilization wedge concept is one that many analysts have found useful in illustrating that no individual policy or technology is likely to be sufficient to achieve stabilization of atmospheric GHG concentrations, and that investment in a portfolio of strategies across key emissions-emitting sectors will be necessary to limit GHG concentrations in the atmosphere compared to a business-as-usual approach. However, NHTSA's regulatory authority in the context of this rulemaking is limited to choosing an appropriate standard for CAFE, based on the four statutory factors mandated in EPCA. Thus, a comparison of various CAFE alternatives to other GHG mitigation approaches (e.g., those conceptualized as wedges) is beyond the scope of the EIS (as mandated by NEPA) and the rulemaking.

10.3.3.2 MAGICC Model

Comments

Comment Number: 0572-31
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

MAGICC [Model for Assessment of Greenhouse Gas-induced Climate Change] is used to estimate the increase in CO_2 concentration, global mean temperature, and sea level rise. The DEIS uses the SRES A1B-AIM scenario as a "baseline." The only comparisons in the DEIS are among the three SRES "business as usual" scenarios: B1, A1B, and B2. This analysis, however, is incomplete because it ignores the fact that in order to avoid catastrophic climate impacts greenhouse gas concentrations must be quickly reduced back to below 350 ppm. SRES A1B-AIM results in CO_2 concentrations of 715 ppm in year 2100—far above dangerous CO_2 levels. A more appropriate comparison would be one of the "WRE" stabilization scenarios that are included in the MAGICC software. These stabilization scenarios are provided for 350 to 750 ppm stabilization.

Regardless of the baseline that is selected, the numerical results do not accurately reflect the state of the science. The DEIS relies heavily on the IPCC's Fourth Assessment Report, published in 2007. The model version used for numerical analysis, however, is calibrated to the Third Assessment Report, which was published in 2001. The MAGICC software has been updated to reflect the values reported in the

Fourth Assessment report; the newest version is MAGICC 5.3. This update has important changes from version 4.1. These changes include:

- Values for climate forcings were updated and two new forcings for nitrates and land use were included
- The stabilization scenarios now include stabilization strategies for non-CO_2 gases as well as CO_2
- The method of sea level rise was improved to be more consistent with the IPCC Fourth Assessment Report
- Default climate sensitivity was changed from 2.6 °C to 3.0 °C, in conformance with the Fourth Assessment Report.

Most importantly, the modeling results should be presented with the disclaimer that non-linear responses are not included in the predictions. Emphasis should be placed on the fact that (1) the model does not capture actual sea level rise predictions because it does not include ice sheet dynamics and (2) the model does not include the impact of rapid increases in methane from widespread loss of permafrost.

Comment Number: 0572-33
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The "scaling approach" as applied to sea level is also misleading. First, MAGICC 5.3 reports increments of sea level rise of 0.1 mm – not 1 mm as reported in the DEIS. Thus, the MAGICC results can resolve sea level rise to the same precision as the "scaling approach."

Comment Number: 0595-23
Organization: Environmental Protection Agency
Commenter: Susan Bromm

While EPA believes that the overall methodology used by NHTSA to model climate effects for the different CAFE scenarios using MAGICC is sound, EPA does have some recommendations that would strengthen the analysis performed. EPA would recommend re-running the analysis using the revised version (5.3) of MAGICC, which incorporates climate models used in IPCC's Fourth Assessment Report. We would also suggest running MAGICC using a range of climate sensitivities to reflect the 2.0-4.5 °C range projected in the IPCC report.

Response

NHTSA has updated the analysis using MAGICC 5.3 (which was not available when analysis for the DEIS started) and has run other baseline scenarios and climate sensitivities (2.5 ºC, 3.0 ºC, and 4.5 ºC for doubled CO_2) to illustrate the uncertainty of the emissions reductions on key climate effects such as global temperature increase, CO_2 concentrations, and sea level. NHTSA recognizes that MAGICC 5.3 does not incorporate the latest information on sea-level rise, and has noted this in the FEIS.

NHTSA included the scaling approach in the DEIS because MAGICC 4.1 did not reflect the latest results in the IPCC Fourth Assessment Report. Because the FEIS uses MAGICC 5.3 (which is updated to *reflect Fourth Assessment science), it eliminates the scaling approach, but includes an expanded comparison of MAGICC 5.3 and the Fourth Assessment results.*

Given that MAGICC 5.3 generates sea-level rise estimates in increments of 0.1 mm, rather than 1 mm, the FEIS provides outputs at this level of resolution, as recommended by the commenter.

In terms of stabilization targets, the FEIS expands the discussion of tipping points to include a brief review of the European Union's recent proposed target of 450 ppm CO_2 equivalent and 2 ºC. The discussion notes that improvements in vehicle efficiency will be only one of many steps required to meet such a target. See Section 3.4.3.2.4.

Regarding non-linear climate responses and abrupt changes in climate, the FEIS includes an expanded discussion of tipping points that acknowledges the limitations in current simulations of sea-level rise (particularly in relation to ice-sheet dynamics), and the incomplete characterization of positive feedbacks (such as CH_4 [methane] emissions from permafrost). See Section 3.4.3.2.4.

10.3.3.3 IPCC Scenarios

Comments

Comment Number: 0572-32
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The "scaling approach" used in the DEIS is intended to test the effect of intermediate emissions scenarios. This is accomplished through linear interpolation between the relative outputs of three SRES scenarios: B1, A1B, and A2. This same estimate can be obtained by designating a "GAS" file in MAGICC that has intermediate CO_2 emissions.

From the skeletal description in the DEIS, it appears that (in a nutshell) the process involves taking the difference between the annual emissions (inputs) and the outputs (temperature, sea level, CO_2 concentration) associated with each of the SRES scenarios. The percentage change from "baseline" emissions for each alternative is then used to scale the outputs from the baseline scenario. See DEIS at 3-50. At a minimum, the calculation explanation must be improved, preferably with step-by-step examples to make the calculation accessible to the general public, as required by NEPA.

The underlying assumption to this process is that a linear transform will adequately describe the response to a change in emissions levels. Yet, as acknowledged in the DEIS at 3-52, climate interactions are non-linear. To test the linearity of the change between SRES scenarios, we ran an intermediate scenario in which the input annual carbon emissions were set at the midpoint between B1and A1B. We then plotted the output variables. Examples are shown below. [See original comment document for examples.] The numerical differences between each of the SRES scenarios and the intermediate scenario were not symmetrical. This indicates that climate outputs are not linearly related to emissions levels, violating the assumption of linearity upon which the scaling approach is based.

As acknowledged in the DEIS, the climate system is non-linear. DEIS at 3-52. Thus, it is not surprising that a linear transform between SRES scenarios is an inaccurate approximation of climate response.

Of course, comparing the scaling approach to MAGICC outputs assumes that MAGICC has accurately approximated the dynamics of the climate system. It seems likely, however, that MAGICC is the superior approximation. The MAGICC simulation routine has been extensively used by the IPCC and subjected to peer review. In contrast, no citations are provided in the DEIS that indicate the "scaling approach" has been subjected to similar scrutiny. Thus, the NHTSA should consider the MAGICC outputs more reliable. Furthermore, the DEIS provides no explanation why the "scaling approach" was deemed necessary.

Comment Number: 0572-35
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The scaling approach purports to correct for "overstatements" due to inertia in the climate system. Yet an apparent "bias" is *created* by applying the "scaling approach" from the DEIS. If an accepted model such as MAGICC is employed, the effects of climate inertia will be properly accounted for without being overly represented in the results. Thus, the solution to "overstatements" of climate inertia is to avoid using the scaling approach.

The scaling approach as applied to sea level change uses inaccurate values from Table 3.4-7, the temperature "scaling approach" results. When compared to the results from MAGICC at differing climate sensitivities, the scaling approach results in smaller differences in temperatures between alternatives. This in turn pollutes the results from the sea level scaling approach, making the sea level differences seem smaller.

Comment Number: 0585-9
Organization: Attorneys General of the States of California, Massachusetts, New Jersey, New Mexico, New York, and Oregon, Secretary of the Commonwealth of Pennsylvania Department of Environmental Protection, and New York City Corporation Counsel
Commenter: Edmund Brown Jr., Joseph Powers, Martha Coakley, Michael Cardozo, Anne Milgram, Gary King, Andrew Cuomo, Hardy Myers

The DEIS does not answer the ultimate question of whether the agency has adequately considered our need to reduce GHG emissions and to stabilize CO_2 concentrations.

In the end, neither the Agency nor the public can assess the impact of the CAFE rule on global warming unless the data are put into a meaningful context, which the DEIS has failed to do. One way to remedy this fundamental defect would be to refer to the various emissions scenarios modeled by the IPCC as a kind of a comparative baseline. These scenarios include the "business as usual" scenario, usually represented by the IPCC's A1B scenario, which assumes rapid economic growth, peak population by 2050, declining thereafter, rapid introduction of new, more efficient technologies, and a balanced use of both fossil and non-fossil fuels. [Footnote: See original comment document. The A1B scenario stabilizes CO_2 concentrations at 720 ppm by 2100 and is associated with additional warming of 2 to 4 degrees Celsius [Footnote: See original comment document.], which puts us well into the region of likely dangerous anthropogenic interference. [Footnote: See original comment document.]

The IPCC's "alternative" scenarios are those in which human inputs to global warming are constrained to varying degrees and the effects of global warming are mitigated to greater and lesser extent. In particular, the B1 scenario will reduce GHG emissions below 1990 levels well before 2100 and will maintain CO_2 concentrations below 550 ppm. [Footnote: See original comment document.] Under this alternative scenario, GHG emissions could continue to increase briefly, but would need to level out quickly, and decline before 2050, in order to allow for the possibility of adaptation that will avoid a catastrophic disruption of life on Earth. In order to stabilize CO_2 concentrations below 450 ppm, emissions would have to be lowered even sooner, with emission levels peaking by 2020 and then declining sharply. Even at this level, scientists predict warming of 2.0 degrees Celsius and sea level rise of half a meter or more by 2100. [Footnote: See original comment document.]

In the DEIS, NHTSA views the IPCC A1B scenario as representing the “no-action alternative.” DEIS at 3-51, 4-24. As noted above, NHTSA simply subtracts the changes in GHG emissions attributable to the various CAFE alternatives from the A1B emissions scenario to determine the effect on CO_2 concentration and temperature. See DEIS at 4-22, 4-51.

This analysis, however, is not meaningful, because it does not inform the reader whether the actions of the Agency, coupled with anticipated actions of other agencies, will be sufficient to change our trajectory from the A1B “no-action” scenario, to the B1 scenario of stabilized CO_2 concentration and temperature. Thus, neither the agency nor the public can determine whether NHTSA has considered and given sufficient weight to the dangers of global warming in setting the CAFE standard at the “optimized” level, rather than at a higher level.

In order to answer the latter question, NHTSA must consider its actions within the context of the steps that are being taken or are reasonably foreseeable to be taken by all agencies, organizations, nations, and localities to prevent CO_2 concentrations in the atmosphere from reaching a level of dangerous anthropogenic interference. As noted above, it is generally agreed that, in order to maintain CO_2 concentrations at the 500 ± 50 ppm level, emissions must stabilize and begin to decline either by 2020 or 2050. Given this consensus, the DEIS should calculate what CAFE mileage standard would have to be reached by those dates, taking into account anticipated increases in VMT, in order to stabilize and reduce GHG emissions from passenger cars and light trucks. The DEIS must then determine whether the new CAFE rule moves us forward sufficiently so that we will be poised to reach the required future goals. If the proposed CAFE rule will not enable us to stabilize and begin to reduce emissions by 2020 or 2050, then what CAFE standard is necessary now to enable us to achieve the future reductions?

Comment Number: 0595-24
Organization: Environmental Protection Agency
Commenter: Susan Bromm

For the emissions scenarios analyzed, EPA would suggest using A2, A1B, A1FI, and B2. We would suggest adding some text indicating that recent socioeconomic and emissions trends are higher than those captured by SRES and even more recent scenarios.

Additionally, EPA has the following questions and comments regarding the climate projections used by NHTSA:

1. Why was the SRES MB chosen as the baseline scenario? How does it compare to current trends? Other potential futures should be considered.
2. What climate sensitivity was used? If only a climate sensitivity of 3 was considered, then NHTSA has ignored the implications for the distribution of potential climate outcomes in 2030, 2060, and 2100.
3. There are inconsistencies in the treatment of climate and other analyses:
    a. NHTSA is using an SRES A1B emissions scenario for climate projections, yet using a mean SCC estimate based on a variety of climate projections;
    b. NHTSA is combining a domestic estimate of the SCC with global climate variables; and

c. NHTSA is using SRES A1B emissions for global climate, yet is using U.S. EPA emissions for transportation which are not consistent with A1B.

Response

For the FEIS analysis, NHTSA used MAGICC Version 5.3. NHTSA also has responded to the suggestions to use multiple scenarios from the Special Report on Emission Scenarios (SRES) to simulate the base case (the No Action Alternative) emissions corresponding to a variety of socioeconomic and emissions trends, and comments suggesting running other baseline scenarios and climate sensitivities (2.5 ºC, 3.0 ºC, and 4.5 ºC) to illustrate the uncertainty of the emissions reductions on key climate effects such as global temperature increase, CO_2 concentrations, and sea-level rise.[23] Section 3.4 of the FEIS incorporates all of these results to show the sensitivity of results to different assumptions on base-case emissions and climate sensitivity. In addition, by definition, the IPCC SRES scenarios exclude any global policy to reduce emissions and avoid climate change but might include other policies that could impact GHG emissions. Even the B1 family of scenarios is defined as follows in the IPCC SRES report: "[t]he emphasis is on global solutions to economic, social, and environmental sustainability, including improved equity, but without additional climate initiatives." (Nakicenovic et al. 2000).

Regarding attaining stabilization of atmospheric CO_2 concentrations below 500 ppm (or any other target suggested by commenters), GHG reductions in any one sector and any one nation will not be sufficient to stabilize at these levels, and it is clear that none of the alternatives evaluated in the FEIS would meet such an objective. NHTSA recognizes that several approaches have been put forth for developing comprehensive, multi-sector strategies to reduce GHG emissions. However, NHTSA's regulatory authority in the context of this rulemaking is limited to choosing an appropriate CAFE standard, based on the four statutory factors mandated in EPCA. Thus, a comparison of various CAFE alternatives to other GHG mitigation approaches (e.g., those conceptualized as wedges) is beyond the scope of the EIS and the rulemaking.

NHTSA included the scaling approach in the DEIS because MAGICC Version 4.1 did not reflect Fourth Assessment Report science. Because the FEIS uses MAGICC Version 5.3, it eliminates the scaling approach and includes an expanded comparison of MAGICC Version 5.3 and Fourth Assessment Report results.

10.3.3.4 Non-CO_2 GHGs

Comments

Comment Number: 0572-38
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

Although the DEIS quantifies CO_2 emissions, it utterly fails to address black carbon, an important short-lived pollutant that contributes to global and regional warming. Black carbon is produced by incomplete combustion and is the black component of soot. Although combustion produces a mixture of black carbon and organic carbon, the proportion of black carbon produced by burning fossil fuels, such as diesel, is much greater than that produced by burning biomass. The CAFE standards will affect both gas and diesel engines, and may result in a higher percentage of diesel-fueled vehicles. Thus, it is essential to consider the impact of the new standards on black carbon emissions.

---

[23] *The SRES scenarios are long-term emissions scenarios representing different assumptions about key drivers of GHG emissions. Section 3.4 of the FEIS describes the SRES scenarios in more detail.*

Black carbon heats the atmosphere through a variety of mechanisms. First, it is highly efficient at absorbing solar radiation and in turn heating the surrounding atmosphere. Second, atmospheric black carbon absorbs reflected radiation from the surface. Third, when black carbon lands on snow and ice, it reduces the reflectivity of the white surface which causes increased atmospheric warming as well as accelerates the rate of snow and ice melt. Fourth, it evaporates low clouds. Notably, black carbon is often complexed with other aerosols such as sulfates, which greatly increases its heating potential. (Ramanathan & Carmichael 2008; Jacobson 2001)

Due to black carbon's short atmospheric life span and high global warming potential, decreasing black carbon emissions offers an opportunity to mitigate the effects of global warming trends in the short term (Ramanathan & Carmichael 2008). Black carbon is considered a 'short-lived pollutant'(SLP) because it remains in the atmosphere for only about a week in contrast to carbon dioxide, which remains in the atmosphere for over 100 years. Furthermore, the global warming potential of black carbon is approximately 760 times greater than that of carbon dioxide over 100 years (Reddy & Boucher2007) and approximately 2200 times greater over 20 years (Bond & Sun 2005). It is estimated that black carbon is the second greatest contributor to global warming behind carbon dioxide (Ramanathan & Carmichael 2008).

Unlike traditional greenhouse gases, which become relatively uniformly distributed and mixed throughout the Earth's atmosphere, black carbon exerts a regional influence. The impacts of black carbon on a regional level include both atmospheric heating, as discussed above, and hydrological changes. Hydrological changes occur due to alterations in cloud formation and heat gradients (Ramanathan & Carmichael 2008). For instance, aerosol pollution has been linked to decreases in the summer monsoon season in tropical areas as well as the drought in the Sahel region of Africa (Ramanathan & Carmichael 2008). Black carbon also impacts the drought-fire cycle. The more drought conditions prevail, the more forest fires burn, and the forest fires in turn emit massive quantities of black and organic carbon. The release of these aerosols intensifies the drought effect.

Another impact of black carbon is accelerated snowmelt; for instance, black carbon is likely contributing to the retreat of Himalayan glaciers and the resulting water shortage in areas of Asia (Ramanathan & Carmichael 2008). When black carbon settles on snow, it makes the snow darker so that it absorbs more solar radiation. This directly leads to snow melt. In addition, local atmospheric heating due to black carbon increases the melting rate. These same effects may well be operating on mountain ranges in the U.S. such as the Sierra Nevada, which would reduce water availability throughout California, a highly populated region, at crucial times of the year.

Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

NHTSA states, on page 24413 of the NPRM, that "[for] purposes of this rulemaking, NHTSA estimated emissions of vehicular CO_2 emissions, but did not estimate vehicular emissions of methane, nitrous oxide, and hydroflourocarbons. Methane and nitrous oxide account for less than 3 percent of the tailpipe GHG emissions from passenger cars and light trucks, and CO_2 emissions accounted for the remaining 97 percent. Of the total (including non- tailpipe) GHG emissions from passenger cars and light trucks, tailpipe CO_2 represents about 93.1 percent, tailpipe methane and nitrous oxide represent about 2.4 percent, and hydroflourocarbons (i.e., air conditioner leaks) represent about 4.5 percent." Although these emissions make up a relatively small portion of the total greenhouse gas emissions from automobiles, they nonetheless represent large amounts of greenhouse gases and must be included in both the economic and environmental analyses. For example, nitrous oxide emissions with greenhouse gas impacts equivalent to 29 million metric tons of CO_2 are far from insignificant.

Comment Number: 0595-21
Organization: Environmental Protection Agency
Commenter: Susan Bromm

Finally, EPA is concerned that NHTSA has not accounted for non-$C0_2$ GHG emissions changes that would be expected with the policy, e.g., changes in fuel use will bring changes in non-$C0_2$ GHG emissions associated with fossil fuel extraction, production, transportation, refining, and combustion.

Response

NHTSA has added a discussion of black carbon to the FEIS. See Section 3.4.4.4.2. This discussion notes that while MAGICC 5.3 estimates radiative forcing from black carbon, emissions trends for black carbon are assumed to bear a fixed relationship to emissions of SO_2 and cannot be specified separately in the model. The tailpipe emissions factors derived by Volpe using MOBILE6.2 include both "elemental carbon" and "organic carbon" as components of both $PM_{2.5}$ and DPM emissions, although emissions of individual PM components were not estimated or reported separately.

The FEIS includes estimates of methane and nitrous oxide emissions, and the emissions reductions (related to the No Action Alternative) were included in the climate modeling analysis. NHTSA did not estimate emissions from HFCs, which are not expected to change substantially as a result of the CAFE rule. NHTSA has revised Section 3.4.3.1 of the FEIS to make clear that emissions estimates include non-CO_2 gases (CH_4 and N_2O) and include upstream sources of emissions of CO_2 and these non-CO_2 gases. In addition, NHTSA has clarified that the following non-GHGs were also estimated by the Volpe model and accounted for in the climate modeling: SO_2, NO_x, CO, and VOCs.

10.3.3.5 Consequences

Comment

Comment Number: 0585-4

Commenter: Edmund Brown Jr., Joseph Powers, Martha Coakley, Michael Cardozo, Anne Milgram, Gary King, Andrew Cuomo, Hardy Myers

The DEIS improperly compares the decrease in growth of emissions from the CAFE rule with the absolute decrease in emissions from the U.S. regional programs, creating a false impression of the benefits of the rule.

The DEIS further misleads the public by setting up a false comparison between the reduction in growth of GHG emissions from the CAFE alternatives, and the absolute decrease in emissions from the climate programs created by groups of states such as the Western Climate Initiative ("WCI") and the Regional Greenhouse Gas Initiative ("RGGI"). DEIS at 3-57, 4-28 to 4-29. For example, in the cumulative impacts section, the DEIS states that the WCI has a goal of reducing CO_2 equivalent emissions by 350 million metric tons ("MMT") from 2009 to 2020, and the CAFE rule will reduce CO_2 emissions by 455-830 MMT over the same time period. The DEIS further states that the RGGI will reduce CO_2 emissions by 268 MMT from 2006 to 2024 and the CAFE rule will reduce CO_2 emissions by 1,100-1,834 MMT over the same time frame. The DEIS therefore concludes that "the alternatives analyzed here deliver GHG emission reductions that are on the same scale as many of the most progressive and ambitious GHG emission reduction programs underway in the United States." DEIS at 4-29.

The above analysis, and in particular, the latter statement, are affirmatively misleading. The regional goals represent absolute reductions from prior levels. In reducing CO_2 equivalents by 350 MMT, the WCI is actually committed by 2020 to bringing its level of emissions 15% below the levels that existed in 2005. See Western Climate Initiative, Statement of Regional Goal, 2007 at 1. [Footnote: See original comment document.] Similarly, the RGGI will result in a 2018 emissions budget that is 10% smaller than the 2009 emissions budget. See Overview of RGGI CO2 Budget Training Program, October 2007 at 2. [Footnote: See original comment document.] In contrast, the emission figures cited by NHTSA as attributable to the CAFE rule actually represent a significant increase above previous levels. In order to be "on the same scale as many of the most progressive and ambitious GHG emission reduction programs underway in the United States," the CAFE rule would have to reduce the level of GHG emissions below existing levels. Clearly, no such reduction is envisioned. In fact, a more accurate statement would be to say that the increase in GHG emissions from previous levels allowed by the CAFE rule would wipe out reductions in emissions achieved by the various regional climate coalitions.

Response

NHTSA has added more analysis to Section 3.4.4.1 of the FEIS to illustrate the change in GHG emissions due to each measure (RGGI and WCI) in terms of percent change from the baseline and percent change from the beginning of each measure. The additional text clarifies that while the RGGI and WCI measures are designed to reduce emissions in relation to both expected future emissions and levels in a base year, the CAFE alternatives reduce emissions from the expected future emissions from cars and light trucks in the United States, and result in continued increases in relation to any given base year that might be chosen. That is, CAFE standards do not reduce GHG emissions from cars and light trucks from base-year emissions levels.

Emissions from cars and light trucks are a function of both fuel economy and vehicle miles traveled. NHTSA's assumptions on growth in future VMT are based on historical trends. Despite the improvement in fuel economy resulting from this rulemaking, the growth in VMT traveled is anticipated to outweigh the improvement in fuel economy, and thus emissions from cars and light trucks are expected to continue increasing.

Nevertheless, it cannot be argued that the alternatives would result in an absolute increase in emissions. Emissions under the alternatives would surely be lower than under the No Action Alternative, and thus, represent a verifiable improvement to the environment.

Commenter: Edmund Brown Jr., Joseph Powers, Martha Coakley, Michael Cardozo, Anne Milgram, Gary King, Andrew Cuomo, Hardy Myers

The DEIS fails to make clear the connection between anticipated CO_2 concentrations and extreme environmental impacts.

The DEIS contains a qualitative discussion in chapter 4 of the potential impacts of global warming, but avoids linking the CAFE rule with particular impacts, noting that the impacts from the rule in isolation are too small to quantify. DEIS at 2-13. While technically correct that the GHG emissions from the CAFE rule in isolation cannot be linked to particular environmental impacts, the DEIS should make clear that the levels of CO_2 concentrations and temperature increase that it anticipates, more than 700 ppm CO_2 and 2.7 degrees Celsius (Table 4.43 at DEIS 4-31), are directly associated with some of the more extreme environmental effects.

One way to explain the connection between the atmospheric concentrations of CO_2 and the increased temperatures anticipated by the DEIS on the one hand, and the real environmental effects on the other, would be to rely on the materials presented by the IPCC. For example, Figure SPM.2 [Footnote: See original comment document.] illustrates graphically how various extreme environmental effects become increasingly likely as temperature rises. Notably, the figure demonstrates that the increase in temperature of 2.7 degrees Celsius anticipated by the DEIS may result in the extinction of more than 20 to 30% of the species on earth, coastal flooding affecting millions of people, increasing burdens from malnutrition and disease, and increased mortality from heat waves, floods, and droughts. This type of graphic representation will, consistent with the purposes of NEPA, enable the reader to understand that, in setting the CAFE standard, NHTSA anticipates that we are potentially on the path to dangerous anthropogenic interference and cataclysmic climate change.

Comment Number: 0596-4
Organization: Environmental Defense Fund
Commenter: Martha Roberts

In this EIS GHG emissions for the CAFE alternatives are presented primarily in terms of the small relative differences among them, instead of the total GHG from the vehicle categories projected for each alternative. This is misleading because it gives the impression that each alternative will progressively decrease the nation's GHG emissions, when in fact, under each alternative total GHG emissions increase considerably compared to the present. Merely demonstrating the relative reductions of stricter alternatives versus "no action" paints a mirage of future benefits that do not exist.

We have conducted a simple analysis that provides this more appropriate contextual information. It demonstrates, for example, that under the "optimized" alternative, atmospheric CO_2 concentrations will increase by approximately 12 ppm by 2100. (This estimation relies upon the cumulative greenhouse gas (GHG) emissions presented in section 4 of the EIS and the assumption that oceans and forests will sequester half of the total GHG emissions. Then each 8,000 MMT CO_2e contributes 1 ppm of atmospheric CO_2e. See the EPA's paper, A Wedge Analysis of the U.S. Transportation Sector (EPA 420-R-07-007, U.S., 2007) for more details.) This is a more appropriate depiction of its impact than showing, as the current EIS does, the tenths of a ppm variation between the different alternatives by 2100. NEPA requires that each proposal, including the "no action" alternative, be considered against the baseline condition so that cumulative impacts, which are defined as both adverse impacts and the enhancement of the environment, can be compared with existing environmental impacts. This comparative analysis is unlawfully omitted from the EIS.

Response

NHTSA included the suggested discussion of impacts from extreme temperature increases from the IPCC Fourth Assessment Report to put the baseline emissions and emissions reductions into context. See Section 3.4.1.4. NHTSA also expanded the discussion of tipping points to address this point. See Section 3.4.3.2.4.

NHTSA disagrees with the interpretation that the Optimized Alternative increases CO_2 concentrations from the baseline. The baseline represents continued increases in emissions from cars and light trucks, consistent with increases in population and income. The CAFE alternatives reduce the CO_2 emissions and concentrations from these levels. The emissions are greater than current emissions, but it is not reasonable to view current conditions as the baseline.

NHTSA added a discussion in this FEIS to better show the emissions reductions from the CAFE standards alternatives as emissions reductions from cars and light trucks in the United States, which shows that it does represent substantial emissions reductions from the transportation emission sector. See Section 3.4.4.1.

10.3.3.6 Sea-level Rise

Comments

Comment Number: 0572-27
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The DEIS cannot rely solely on model results to predict sea level rise. Instead, the prediction should be based on the sea level measurements from paleoclimate data, which indicate that in the past sea level was approximately 25 meters higher at temperatures only 2-3° C of warmer and atmospheric CO_2 concentrations of 350 – 450 ppm. (Hansen 2007). For comparison, the DEIS predicts that temperature in 2100 under the A1B "business as usual" scenario will be approximately 2.7° C warmer. DEIS at 3-63, Table 3.4-5. Although the DEIS acknowledges that Rahmstorf (2007) has predicted a sea level rise of over 1 m by 2100, even his prediction does not capture the non-linearity of ice-sheet loss (Hansen 2007). If this non-linearity is taken into account, "business as usual" sea level rise this century is more likely to be on other order of 5 m (Hansen 2007; Overpeck et al. 2006).

Given the strong scientific evidence that sea level will rise by substantially more than predicted in the IPCC Fourth Assessment report, the EIS's analysis, both qualitative and quantitative, must be adjusted to account for the economic impacts of severe and abrupt climate change. It is certain that sea level will rise significantly this century, and assuredly at a rate much greater than that reported in the DEIS. Regardless of the actual numerical value, the amount of increase will be enough to constitute a major environmental and economic impact. Economic analyses exist to estimate the economic impact of such an event. (Stern 2007) [Footnote: See original comment document.] As a result, the DEIS must include the substantial economic cost in the cost-benefit analysis.

Comment Number: 0572-34
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The example of the scaling approach as applied to sea level and as illustrated in Table 3.4-14 is obscure and impossible to follow. Data appears to be missing from Table 3.4-14 (column 1) and the values do not appear to correspond to the steps outlined on page 3-77. This needs to be clarified so that readers can assess the validity of the numerical results. The value for sea level rise for "no action" corresponds to the midpoint for the B1 scenario (28.0 cm [centimeter]), not the A1B scenario (34.5 cm) that is purportedly represented in Table 3.4-14. If the steps provided on page 3-77 are carried out, it appears that the difference between alternatives for sea level rise is approximately double the range of values reported in Table 3.4-14.

Regardless, the approach itself is deeply flawed. First, using the IPCC estimates of potential sea level rise does not correct the shortcomings in MAGICC. The IPCC did not account for ice sheet dynamics in any of their estimates. As a result, any modeling or scaling attempt will not capture the most important components of sea level rise, as acknowledged in the DEIS at 3-76. As a result any attempt to estimate sea level rise from IPCC data will be deeply flawed. If a scaling approach is to be used, it should be based on paleoclimate data predicting the sea level rise associated with various temperature and CO_2 concentrations.

Response

In Section 3.4.3.2.4 of the FEIS, NHTSA expands its research and consideration of the issue of tipping points to include new research, as suggested by commenters, and expands the discussion from the IPCC and USCCSP literature. NHTSA expands the discussion within the FEIS to include the consideration of paleoclimatic research, which shows that abrupt and severe climate change has occurred in the past, that greater increases in sea-level rise occurred in the past and at temperatures consistent with those being simulated for 2100, and that these climate changes can occur in multiple climate systems or related systems affected by climate. While there is still substantial uncertainty surrounding the exact thresholds where tipping points occur, and the interrelationships among tipping points, scientists are improving their understanding of the processes that determine the potential for abrupt or irreversible change. As noted by commenters, the triggering of abrupt and severe climate-change events could increase the costs to society in an equally abrupt fashion.

Given the current state of science on tipping points, it is not possible for NHTSA to quantitatively relate the reductions in CO_2 emissions, temperatures, precipitation changes, and sea-level rise to tipping-point thresholds. Like all other individual GHG mitigation actions being considered by governments around the world, this action alone, even as analyzed under the most stringent alternative, does not produce enough of a CO_2 emissions reduction to avert levels of abrupt and severe climate change. Abrupt or severe climate change can only be avoided through implementation of many more GHG-reduction initiatives, and will require a global effort. To the degree that the action in this rulemaking reduces the rate of CO_2 emissions, the rule contributes to the general reduction or delay in reaching these tipping-point thresholds. Alternatives that reduce greater amounts of CO_2 contribute a greater degree to the avoidance of any tipping points within global climate systems.

NHTSA included the scaling approach in the DEIS because MAGICC 4.1 did not reflect Fourth Assessment Report science. In the FEIS, NHTSA used MAGICC 5.3 and eliminated the scaling approach, but included an expanded comparison of MAGICC 5.3 and Fourth Assessment Report results.

10.3.4 Resource Impacts of Climate Change

10.3.4.1 Introduction

Comment

Comment Number: TRANS-33-5
Organization: Individual
Commenter: Fred Dobb

Spiritually and ethically, we cannot reduce endangered species, flood and famine refugees, or the integrity of recreation to pennies in an equation, not that the draft EIS even accounts for them at all.

Response

The FEIS discusses the impacts of floods and droughts on the population, both nationally and globally. See Section 4.5.7.1; Section 4.5.7.2; Section 4.5.7.2.1; Section 4.5.8.2.3; and Section 4.5.8.3. While these can certainly be devastating events, the science of directly linking floods and droughts to anticipated changes in climate on the local and regional scale is still developing. A number of endangered species are likewise considered in the DEIS. See DEIS 4.5.4; DEIS p. 4-81, Section 4.5.4.2.3. NHTSA has chosen not to monetize such relationships as the impact upon health and environment because the DEIS and this FEIS focus on changes in, and impacts to, the environment - not on the monetized values of those changes.

10.3.4.2 Industries, Settlements, and Society

Comment

Comment Number: TRANS-37-7
Organization: Individual
Commenter: Jaafar Rizvi

Now, of course, these disasters aren't entirely preventable, but it's within our power to lessen the severity of them.

The DEIS report states that 4 percent of the world's global warming emissions come from American transportation. And if we can lower these emissions by 25 percent, we're lowering the global emissions by 1 percent.

If a decrease in 1 percent could decrease, you know, the severity of the next Katrina by 1 percent, you're talking about saving thousands of lives, and you're talking about saving a billion dollars.

Moreover, we can expect to have more than one large disaster every year. We have been having tons all over the world. Katrina was the last huge one in the U.S. But the International Federation of the Red Cross showed in its 2007 world disaster report that there has been an increase in natural disasters of over 115 percent since 2004, totaling 541 individual disasters. It states that this increase has been due entirely to weather related disasters.

Response

The commenter attempts to establish a causal relationship between global warming and a particular weather event, in this case, Hurricane Katrina. No single weather event can be attributed to global warming, even though global warming can increase the likelihood of some extreme weather events. Because of this and the non-linear nature of global warming, it is not possible to make the connection the commenter tries to make by attributing a reduction in the strength of a storm to an equal reduction in CO_2 emissions. Further, the relationship between emissions levels and weather-related natural disasters is not clear. The state of scientific knowledge is not sufficient at this time to determine how weather-related disasters would be affected by the action alternatives, other than to state that the reduction in CO_2 emissions estimated by this rulemaking would contribute to the reduction of impacts of global warming, including severe weather events.

10.3.4.3 Human Health

Comments

Comment Number: 0596-3
Organization: Environmental Defense Fund
Commenter: Martha Roberts

The cumulative impacts section in this EIS fails to provide the proper context to evaluate the climate change potential or consequent health impacts of the proposed fuel efficiency standards. In omitting this context NHTSA directly contradicts the Court's instructions in *Center for Biological Diversity v. NHTSA* regarding the agency's obligation to address cumulative impacts under NEPA, explaining that the environmental review must:

"provide the necessary contextual information about the cumulative and incremental environmental impacts of the Final Rule in light of other CAFE rulemakings and other past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such other actions." [Footnote: See original comment document.]

The EIS draws heavily upon the most recent Intergovernmental Panel on Climate Change (IPCC) Fourth Assessment Report in describing the causes of climate change and its impacts on the environment and human welfare. However, the EIS ignores the strong language in the IPCC report that describes appropriate, science-based targets to avoid the most drastic of these impacts. For example, the IPCC states that "avoidance of many key vulnerabilities requires temperature change in 2100 to be below 2.6 °C above pre-industrial levels." [Footnote: See original comment document.] Key health-related vulnerabilities include the risk of floods, droughts, and deteriorating water quality and supply for hundreds of millions of people. [Footnote: See original comment document.] Rising global temperatures increase the likelihood of severe weather events, net declines in world food production, and widespread deglaciation with the resultant loss of reliable summer melt stream flows, all detrimental to human health. In order to avoid passing this dangerous temperature threshold, the IPCC indicates that GHG emissions must peak within 10 years (of 2007) and atmospheric carbon dioxide (CO_2) levels stabilize at less than 440 parts per million (ppm). This corresponds to a 30-60% reduction in global GHG emissions by the year 2050 from the year 2000. [Footnote: See original comment document.]

The type of risk management approach, which seeks a reasonable target to avoid severe health, environmental, and other impacts of dangerous climate change, has been proposed by the EPA in its recent "Technical Support Document on the Benefits of Reducing GHG Emissions" and summarized by Environmental Defense Fund in its supplemental comments on the NPRM for the CAFE standards. These comments are attached here and we hereby incorporate them as part of EDF's [Environmental Defense Fund's] comments on the draft EIS.

Comment Number: 0600-5
Organization: Centers for Disease Control and Prevention
Commenter: Sarah Heaton, Andrew Dannenberg

The anticipated effects of increased CAFE standards on the human environment in the United States will occur primarily through the following mechanisms: 1) Fleet emission changes 2) Fuel consumption changes 3) Fleet design changes. To adequately assess the potential impact of CAFE standards on the human environment:

Health impact analysis and modeling of each mechanism is necessary for each of the proposed alternatives.

Fleet Emission Changes and Human Health:

Transportation-related emissions contribute to climate change. CAFE standards can promote the use of alternative technologies in the U.S. and abroad that reduce harmful emissions and, in turn, reduce contributors to climate change and improves human health outcomes. Although some health outcomes of climate change are difficult to predict, others are supported by considerable evidence. Health impacts affected by increasing or reducing contributors to climate change are appropriate for analysis of the human environment pursuant to NEPA.

Health outcomes from climate change, for which quantitative or qualitative impact analysis is possible, should be included in predictive modeling.

Automobile contributions to criteria air pollutants are affected by CAFE standards and such emissions directly affect human health outcomes. Asthma, bronchitis, chronic obstructive pulmonary disease, and cardiovascular disease are some of the most common health outcomes triggered or exacerbated by air pollutants from motor vehicles. Reducing ozone forming emissions, NO_x, and hydrocarbons can improve human health outcomes and reduce medical care costs. The DEIS fails to discern among alternatives regarding the health impacts from emissions/air pollutants. For adequate analysis of impacts to the human environment pursuant of NEPA:

Analysis of the potential health effects from fleet emissions, both acute and chronic, is critical to include in the analysis of alternatives pursuant to NEPA.

Adequate cost/benefit analysis of alternatives should include health costs associated with the acute and chronic effects from auto emissions at each level in the range of alternatives to show both current associated costs and potential savings from reduced emissions.

Comment Number: 0600-10
Organization: Centers for Disease Control and Prevention
Commenter: Sarah Heaton, Andrew Dannenberg

The anticipated effects of increased CAFE standards on the human environment in the United States will occur primarily through the following mechanisms: 1) Fleet emission changes 2) Fuel consumption changes 3) Fleet design changes. To adequately assess the potential impact of CAFE standards on the human environment health impact analysis and modeling of each mechanism is necessary for each of the proposed alternatives.

Fuel Consumption Changes and Human Health:

Decreased demand and consumption of fossil fuel in an environment of increasing costs likely affects economic stability which affects human health outcomes (e.g. “drive or eat”). These health determinants and potential health outcomes should be considered as factors affected by CAFE standards and discussed.

Comment Number: TRANS-32-1
Organization: Environmental Defense Fund
Commenter: James Keck

EDF, while supporting the inclusion of climate change health impacts within the EIS is deeply concerned by the assertion that the agency and its consultants were unable to determine the magnitude of these impacts across the proposed CAFE alternatives, not only on the basis of climate change, but also regarding conventional pollutant health impacts.

Response

Quantifying the impacts of climate change on human health is a complex analysis requiring a thorough understanding of not only the direct impacts of varying each climate stressor on human health, but the indirect impacts associated with multiple climate stressors. The complex ecosystem response further amplifies the potential feedbacks of climate change on human health, making it very difficult to adequately quantify this relationship. This would require significant health and environmental modeling, which could provide results with a large amount of uncertainty and which might rely on science still under development. EPA notes in its comments on the DEIS that a "complete health and environmental impacts analysis would begin with a full scale photochemical air quality modeling to demonstrate the changes in ambient air pollution exposure…. These ambient concentrations would then be fed through a health impacts model…to characterize population exposure and the change in health response…." Furthermore, the CCSP 2008 report entitled "Analyses of the Effects of Global Change on Human Health and Welfare and Human Systems" notes that, "the body of literature [on health impacts of climate change] remains small, limiting quantitative projections of future impacts." It also notes that there is still a need to "[d]evelop quantitative models of possible health impacts of climate change that can be used to explore a range of socioeconomic and climate scenarios." Instead, NHTSA describes the impacts by providing a thorough qualitative description of the current "state-of-the-art" science linking climate change impacts to human health. NHTSA also discusses peer-reviewed studies based on modeling and other rigorous tools that link climate change impacts to human health.

Sections 3.3.1.2, 3.3.1.3, 3.5.4, and 4.5.8 of the FEIS describe impacts to human health. In addition, Section 3.4.3.2.4 of the FEIS includes a discussion of tipping points to describe the most drastic impacts of climate change.

10.3.5 Non-Climate Cumulative Impacts of CO_2 Emissions

10.3.5.1 Consequences

Comment

Comment Number: 0572-36
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The DEIS ignores one of the major, direct impacts of increased atmospheric CO_2: ocean acidification. Carbon dioxide is readily exchanged between the atmosphere and the sea surface. The increase in CO_2 is a direct result of human activity—fossil fuel burning. Due to the fact that the ocean has a carbonate buffer system, an increase in aqueous CO_2 reduces the concentration of carbonate while increasing the concentration of bicarbonate. The direct result is a decrease in ocean pH.

The reduction in free carbonate ions harms organisms that form calcium carbonate shells. There is a profound impact on the *entire* marine ecosystem due to the fact that many calcifying plankton, the basis of the food web, are severely affected by ocean acidification. Furthermore, organisms such as fish also experience direct effects from increased ocean CO_2, which include metabolic, immune, and reproductive dysfunction.

There is an extremely high level of scientific consensus regarding the destructive effects of ocean acidification. A recent comment letter signed by the top 25 marine scientists who study ocean acidification emphasized that the decrease in pH due to un-checked CO_2 emissions will be devastating and irreversible on human time scales (Caldiera and 25 others, 2007).

Ocean acidification has also been recognized by advisory bodies. For instance, the USCOP characterizes climate change as "among the most pressing scientific questions facing our nation and the planet." (USCOP Ocean Blueprint 2004). Furthermore, the USCOP report states that ocean acidification is impairing some organisms and has "potentially profound impacts on marine production and biodiversity" (USCOP Ocean Blueprint 2004). The resulting recommendation is that scientific information be used to modify management strategies. Likewise, the Pew Commission discussed the myriad effects of climate change on marine life, including changes in ocean chemistry. The report stated that the Commission "feels strongly" that the U.S. must reduce its emission of greenhouse gases to limit injury to the marine environment (Pew Oceans Commission Living Oceans 2003).

The oceans have already taken up about 40% of the CO_2 that humans have produced since the industrial revolution, and this has lowered the average ocean pH by 0.11 units (Sabine et al. 2004). Although this number may sound small, it represents a significant change in acidity. The ocean takes up about 30 million metric tons of CO_2 each day (Feely et al., 2008). While pre-industrial levels of atmospheric CO_2 hovered around 280 ppm (Orr et al. 2005)), they have now increased to 380 ppm; if current trends continue they will increase another 50% by 2030 (Turley et al., 2006). Over time, the ocean will absorb up to 90% of anthropogenic CO_2 released into the atmosphere (Kleypas et al. 2006).

Unlike future climate change, the pH change in response to increased atmospheric CO_2 is relatively easy to predict because it involves basic chemical reactions and is unlikely to be affected by global temperature change (McNeil & Matear 2006). Thus, there is a strong consensus in the field that the oceans will undergo extensive acidification as the atmospheric CO_2 concentration rises.

Studies have established that anthropogenic CO_2 is the direct cause of the decrease in ocean pH. For instance, a tracer technique can be used to separate naturally occurring and dissolved carbon from that due to human activity (Gruber et al. 1996). Oceans absorb CO_2 more slowly than humans are currently releasing it. Current levels of anthropogenic CO_2 have virtually guaranteed that ocean pH will continue to decrease in the foreseeable future. Anthropogenic CO_2 emissions will result in a decrease in oceanic pH of 0.4 units by 2100 according to a model based on "business as usual" IPCC scenarios (Caldeira & Wickett 2003). This would constitute a catastrophic pH level (Zeebe et al. 2008). Disastrous impacts to marine ecosystems can only be avoided with rapid reductions in CO_2 emissions (Zeebe et al. 2008).

Despite the strong scientific consensus and direct connection between CO_2 emissions and oceanic pH, the DEIS treats ocean acidification as an indirect, cumulative impact. This is unacceptable. The ecological impacts of the proposed CAFE standards on ocean acidification must be fully analyzed. Ocean acidification is even more predictable than changes in temperature or sea level rise, for instance. Yet, the DEIS makes no effort to quantify the influence of the alternatives on ocean pH.

Response

Section 4.7.2.1 of the FEIS includes a discussion of ocean acidification. In addition, Section 4.7.1 describes a projected decrease in ocean pH.

10.3.6 Other Potentially Affected Resources Areas

10.3.6.1 Biological Resources

Comment

Comment Number: 0572-44
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The rulemaking will impact listed species in ways beyond global warming and ocean acidification. For example, vehicles are a primary source of excess nitrogen in the environment. Excess nitrogen contributes to major environmental problems including reduced water quality, eutrophication of estuaries, nitrate-induced toxic effects on freshwater biota, changes in plant community composition, disruptions in nutrient cycling, and increased emissions from soil of nitrogenous greenhouse gases (Fenn et al. 2003). Nitrogen deposition therefore impacts species listed under the Endangered Species Act in a number of ways.

Nitrogen deposition has contributed to the severe decline of the threatened bay checkerspot butterfly, endemic to the San Francisco Bay Area. (Fenn et al. 2003) The bay checkerspot butterfly is restricted to outcrops of serpentine rock which are low in nitrogen and support a diverse native grassland with more than 100 species of forbs and grasses, including the butterfly's host plants. (Fenn et al. 2003) Nitrogen deposition in the soil creates a more hospitable environment for non-native grasses which crowd out the butterfly's host primary host plant, *Plantago erecta*. (Fenn et al. 2003)

Response

Sections 3.5.1 and 3.5.2 of the FEIS acknowledge the influence of petroleum combustion in the introduction of nitrogen to waterbodies and terrestrial ecosystems, and the negative effects of this introduction on aquatic and terrestrial habitats. Additionally, NHTSA has expanded the text in Section 3.5.2.1.4 to mention the potential influence of nitrogen and other air pollutants on sensitive species and habitats. As stated in Section 3.5.2, NHTSA continues to believe that the proposed rule will minimally affect the deposition of nitrogen and resulting impacts to water and biological resources. See *Section 3.3 and Appendix B-1 for more discussion of changes in air-pollutant levels.*

On May 15, 2008, the U.S. Fish and Wildlife Service listed the polar bear as a threatened species throughout is range due to global warming. Endangered and Threatened Wildlife and Plants, Determination of Threatened Status for the Polar Bear (*Ursus maritimus*) Throughout its Range, 73 Fed. Reg. 28212-28303 (May 15, 2008). The NHTSA must consult on the impact of its rulemaking, and its proposal to set fuel economy standards far below what is technologically achievable, on the polar bear. (At the same time that the Secretary published the Final Listing Rule he also issued separate regulations, pursuant to Section 4(d) of the ESA, 16 U.S.C. § 1533(d), which authorize the widespread incidental take of polar bears and purport to exempt greenhouse gas pollutants from Section 7's consultation requirements. Endangered and Threatened Wildlife and Plants, Special Rule for the Polar Bear, 73 Fed. Reg. 28306-28318 (May 15, 2008) ("4(d) Rule"). In a section of the 4(d) Rule entitled "Consultation under Section 7 of the ESA," the Secretary alleges that "the best scientific data currently available does not draw a causal connection between GHG emissions resulting from a specific Federal action and effects on listed species or critical habitat by climate change, nor are there sufficient data to establish the required causal connection to the level of reasonable certainty between an action's resulting emissions and effect on species or critical habitat." 73 Fed. Reg. 28306, 28313. NHTSA must not rely on this rule as an excuse to forgo consultation because it is contrary to the best available science and the legal standards for Section 7 consultation. Moreover, exempting greenhouse gas emitting actions from Section 7 cannot be legally accomplished through section 4(d) of ESA. The Center and co-plaintiffs are currently challenging the 4(d) rule in court. See, e.g. Second Amended Complaint in *Center for Biological Diversity v. Kempthorne*, Civ. No. 08-1339 (CW) (N. Dist. Cal.).)

On May 9, 2006, the National Marine Fisheries Service listed the staghorn and elkhorn corals as threatened due in part to increasing ocean temperature and ocean acidification due to anthropogenic greenhouse emissions. 71 Fed. Reg. 26852. The NHTSA must consult on the impact of its rulemaking on these coral species. The NHTSA must also consult on the impact of its rulemaking on the polar bear's and the corals' critical habitat, once such habitat is designated.

Global warming was cited by the U.S. Fish and Wildlife Service in its critical habitat rulemakings for the Quino Checkerspot and Bay Checkerspot butterflies. See 73 Fed. Reg. 3328-3373 and 72 Fed. Reg. 48178-48218. The NHTSA must consult on the impact of its rulemaking on these species and their critical habitat.

The NHTSA must not limit its consultation, however, to species like the polar bear, corals, and checkerspot butterflies for which anthropogenic greenhouse emissions were cited as a reason for listing or as an impact in the listing or critical habitat rules. The Center has identified 143 listed species for which a recovery plan has been adopted that specifically identifies climate change or a projected impact of climate change as a direct or indirect threat to the species, as a critical impact to be mitigated, as a critical issue to be monitored, and/or as a component of the recovery criteria. [See Exhibit A in original comment document.] This is clear evidence that the NHTSA's rulemaking "may affect" these species. The NHTSA must consult on the impact of its action all listed species which may be affected.

While we are cognizant that federal agencies, for the most part, have not to date been complying with their obligation to consult on the impact of their greenhouse gas emissions on listed species, and therefore there may be some capacity building required for this consultation, this can in no way be used an excuse for continued non-compliance with the law. The direct, indirect, and cumulative impacts of setting fuel economy standards for all cars and light trucks nationally are extraordinarily significant, and therefore a large number of species may be implicated. Where, as here, the NHTSA's rulemaking is national in scope, the NHTSA should conduct a nationally focused consultation. Again, the NHTSA must not attempt to use the large scale of its action as an excuse for ignoring its environmental review duties, since the highly significant nature of the action only makes it more important to thoroughly review its impacts under all applicable laws. Nor can the mere fact that a large geographical area or large number of species be used as an excuse for inaction. See, e.g., *Wash. Toxics Coalition v. EPA*, 413F.3d 1024 (9th Cir.

Wash. 2005) (upholding order requiring the EPA to consult on the impact of 54 pesticide ingredients on 25 species of fish.). If anything, a nationally focused consultation will provide the opportunity to most efficiently analyze the impact of the rulemaking on species and groups of species.

Comment Number: 0572-42
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The NHTSA's rulemaking will impact species listed as threatened and endangered in several ways, yet the NHTSA has failed to initiate the required Section 7 consultations with the Services [U.S. Fish and Wildlife and National Marine Fisheries Services] on its impact. The NHTSA must initiate and complete the required Section 7 consultations on the rulemaking, or it may be held liable for take of listed species from the impacts of its action, including increased greenhouse gas emissions and other emissions such as NO_x.

Comment Number: 0572-48
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

Setting fuel economy standards for U.S. automobiles is one of the single greatest actions impacting overall greenhouse gas emissions in this country. NHTSA's regulations authorize billions of metric tons of CO_2 and other greenhouse gas emissions over the lifetime of the vehicles. As such, NHTSA must initiate consultation with the FWS and NMFS on the impact of the greenhouse gas and other air pollutants on listed species. Without a non-jeopardy biological opinion and incidental take statement, NHTSA may be liable for take of listed species from increased greenhouse gas emissions and global warming that result from the NHTSA's action. Additional information on the requirement for NHTSA to conduct an ESA Section 7 consultation is contained in Attachment 2 [See original comment document for attachment.], consistent with NHTSA's request to limit primary comments to 15 pages or less. 73 Fed. Reg. 24476.

Response

The CBD submitted comments asking NHTSA to complete a Section 7 consultation with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service because, according to CBD, NHTSA's action will impact endangered species. Specifically, CBD argues that NHTSA's action is responsible for "…increased greenhouse gas emissions and other emissions such as NO_x." NHTSA's action actually reduces the rate of emissions by increasing fuel economy, evidenced by overall (tailpipe and upstream) decreases in emissions of NO_x, $PM_{2.5}$, SO_x, VOC, DPM, benzene, and 1,3-butadiene. However, in the FEIS, NHTSA estimates that VMT will increase over time as the per-mile costs decrease (called the rebound effect). Consequently, the Nation's total car and truck emissions are expected to increase. To be accurate in calculating future scenarios, NHTSA must account for this factor, even if the amount of automobile use is beyond NHTSA's control.

Federal agencies are responsible for determining whether consultation on their proposed actions is required. To make this determination, an agency examines the direct and indirect effects of its proposed action to see if the action "may affect" a listed species. For indirect effects, the impact to the species must be later in time, must be caused by the proposed action, and must be reasonably certain to occur.[24]

[24] *Letter from the Director of the Fish and Wildlife Service to the Regional Directors regarding "Expectations for Consultations on Actions that Would Emit Greenhouse Gases" dated May 14, 2008.*

All of the action alternatives analyzed in this FEIS show a reduction in emissions of CO_2, NO_x, $PM_{2.5}$, SO_x, VOC, DPM, benzene, and 1,3-butadiene compared to the No Action Alternative. The FEIS also quantifies the resulting decreases in sea-level rise, changes in precipitation, and temperature decreases for each of the alternatives from decreasing CO_2 emissions. NHTSA then qualitatively discusses the impacts to ecosystems, ocean acidification, natural resources, wildlife, and many other factors. Because it is beyond the ability of current modeling and the level of uncertainty is very high, it is not possible to quantitatively calculate the effects of this CO_2 reduction on specific localized ecosystems. NHTSA discussed the issue with the U.S. Fish and Wildlife Service to ensure proper compliance. Without sufficient data to establish the required causal connection (to the level of reasonable certainty) between the proposed rulemaking, GHG emissions, and the subsequent impacts to listed species or critical habitat, Section 7 consultation is not required.

10.3.6.2 Land Use and Development

Comment

Comment Number: 0595-8
Organization: Environmental Protection Agency
Commenter: Susan Bromm

Finally, the DEIS states that impacts to land use and development "could include increased agricultural land use" due to increasing use of biofuels. Increased mining is also a potential impact as the search grows for raw materials to create new lightweight materials and hybrid structures. Mining and related land disturbance activities could also have an impact on water resources and aquatic health, particularly where increasing sediment runoff in rivers and streams is an issue.

Response

NHTSA has revised Sections 3.5.1 through 3.5.3 and Section 3.5.5 to include a discussion of mining and related land disturbances.

10.3.6.3 Need for Additional Health Impacts Analysis

Comments

Comment Number: 0595-26
Organization: Environmental Protection Agency
Commenter: Susan Bromm

Also, the $/ton source needs to be cited throughout the document and characterized appropriately. EPA used these $/ton estimates in its ozone NAAQS analysis to *supplement* the formal health impacts analysis — they were not used as a substitute for that analysis.

In light of these observations, EPA recommends the text be revised as follows:

> "NHTSA's analysis of alternative CAFE standards incorporates the economic value of reduced damages to human health that would result from the reductions in emissions of criteria air pollutants and GHGs estimated to result from each alternative. These reductions in damages to human health are valued using estimates of damage costs per unit of emissions of each pollutant that approximate the chemical composition

> and geographic distribution of emissions generated by motor vehicle use arid by production and distribution of transportation fuels.
>
> "The dollar-per-ton estimates only provide a screening-level approximation of the potential value of health improvements associated with each alternative. They are not meant to replace a formal health impacts analysis that quantifies and monetizes health incidence such as premature mortality, chronic bronchitis, and respiratory and cardiovascular illnesses, but instead provide an estimate of health-related benefits in the absence of a formal analysis. It should also be noted that the monetized benefits associated with criteria pollutant reductions underestimate total benefits because the dollar-per-ton values used in this analysis omit a number of unquantified human health and environmental impacts.
>
> "The dollar-per-ton estimates used in this analysis were developed by EPA for use in a supplemental analysis of the benefits associated with the final ozone NAAQS RIA [NHTSA should insert the following footnote: U.S. Environmental Protection Agency. August 2007. Benefit Per Ton Technical Support Document, Docket No. EPA-HQ-OAR-2006-0834, Proposed Regulatory Impact Analysis (RIA) for the Proposed National Ambient Air Quality Standards for Ozone Prepared by: Office of Air and Radiation, Office of Air Quality Planning and Standards.]. Human health is further discussed in Chapters 3 and 4."

Comment Number: 0600-1
Organization: Centers for Disease Control and Prevention
Commenter: Sarah Heaton, Andrew Dannenberg

So that comprehensive impact analysis of the human environment for CAFE standards might be carried out and adequately considered in the assessment:

- Collaboration with public health professionals is suggested for assessment and analysis of the CAFE standards' human health impacts.
- Economic analysis should include health costs associated with the environmental impacts of alternatives. This should be described in the EIS.
- Mitigation analysis for projected public health outcomes is necessary. Current mitigation analysis in the DEIS is insufficient.

Response

Two federal agencies commented on the human health discussions in the DEIS. EPA stated that NHTSA did not perform a complete health analysis. Rather than calling for additional analyses, however, EPA suggested clarifying language be inserted in the text that would explain the level of analysis performed. In particular, EPA notes that a "complete health and environmental impacts analysis would begin with a full scale photochemical air quality modeling to demonstrate the changes in ambient air pollution exposure…. These ambient concentrations would then be fed through a health impacts model…to characterize population exposure and the change in health response…." EPA provided text that explains what analysis NHTSA did and did not perform. By contrast, CDC called for more extensive modeling analysis, recommending that economic analysis of health costs be included and commenting that mitigation analysis is necessary. The CDC draws on the wedge analysis described by

Pacala and Socolow in Science magazine in 2004. CDC also provided specific recommendations regarding human health impacts associated with changes in fleet emissions, fuel consumption, and fleet design. See Sections 10.3.2.4, 10.3.4.3, and 10.3.6.4, which address these specific suggestions.

Sections 3.5.4, 3.3.1.2, 3.3.1.3, and 4.5.8 of the FEIS discuss impacts to human health. NHTSA has provided a thorough description of how emissions can affect human health, specific assessments of the changes in emissions due to the new CAFE standards, and discussions of the impacts to human health from direct, indirect, and cumulative impacts perspectives based on information from IPCC and USCCSP. NHTSA has enhanced the information by including data on the potential health costs reduced under each of the alternatives. See Sections 3.3.2.4.2 and 4.3.3.2.3.

NHTSA appreciates and adopts the language EPA suggested to clarify the level of health analysis performed in Section 3.3.2. NHTSA also notes EPA's description of the extensive photochemical exposure and health analysis that would be required to conduct a full-scale health-impacts analysis.

NHTSA believes that this is a better approach than attempting to conduct more extensive health impacts analysis. The differences in emissions reductions (GHGs and air pollution) and in health costs avoided among the alternatives provide ample information for the decisionmaker, as required under NEPA. It is reasonable to anticipate that human health impacts will mirror these indicators. The information to be gained through the very extensive process of health modeling would not add substantial new information, because the differences in estimated climate effects (temperature, precipitation, and sea-level rise) are small; therefore, changes in the health impacts related to these effects would also be small. Further, the differences between the alternatives will be smaller still, due to the global nature of the problem. Similarly, the screening-level analysis of avoided health outcomes and avoided health costs of criteria pollutants among the alternatives provide ample information for the decisionmaker. Additional levels of analysis would on the other hand introduce substantial new uncertainties as each new level of analysis depends on the previous analysis. Thus existing uncertainties are magnified by multiple levels of analysis.

Section 3.4 describes the climate effects and shows that temperature differences between the alternatives are within 0.02 ºC; differences in precipitation are within 0.02 percent; and sea-level rise is within 0.02 to 0.11 centimeter across the alternatives. In fact, NHTSA does not believe that it is possible to credibly estimate the differences between the alternatives, as discussed in Section 4.4 (Cumulative Impacts). This is supported by the USCCSP 2008 report entitled "Analyses of the Effects of Global Change on Human Health and Welfare and Human Systems." This report, which is one of just 21 "priority" Synthesis and Assessment Products issued by the U.S. Government, notes that, "the body of literature [on health impacts of climate change] remains small, limiting quantitative projections of future impacts." The report also notes that there is still a need to "[d]evelop quantitative models of possible health impacts of climate change that can be used to explore a range of socioeconomic and climate scenarios."

To address CDC's request for additional economic/health impacts analysis, NHTSA has provided more information regarding the health effects due to emission of criteria air pollutants. Specifically, NHTSA has expanded the discussion in Sections 3.3.2.4.2 and 4.3.3.2.3 to include estimates of the economic costs and benefits due to asthma, bronchitis, pulmonary disease, and cardiovascular disease. This analysis is limited to the criteria air pollutants because per-unit health damage estimates are not available for MSATs.

In suggesting further modeling, CDC cites the wedge analysis by Pacala and Socolow (2004) and might, therefore, misconstrue the action NHTSA is taking. NHTSA's action is limited to the CAFE rulemaking. The proposed rulemaking would result in substantial reductions in GHG emissions from *passenger cars and light trucks in the United States, which, when considered in a global context, would result in small changes in temperature, precipitation, and sea-level rise. Under NEPA, this is the action that must be evaluated for environmental impacts. The FEIS does not, and should not, in NHTSA's opinion, account for other emissions-reduction strategies beyond what is reasonably foreseeable, as required under NEPA. Because the United States has not established in law or regulation other emissions-reduction strategies (except the MY 2016-2020 CAFE targets specified in EISA), including presumed improvements in energy efficiency would be speculative. Therefore, NHTSA continues to believe that the appropriate context for analysis of human health impacts is limited to the reduction in emissions resulting from the alternatives specified in the proposed rule.*

Finally, CDC suggested inclusion of health expertise in development of the FEIS. An expert in the area of health research and analysis has been added to the consultant team assisting NHTSA on this effort.

10.3.6.4 Vehicle Downweighting

Comments

Comment Number: 0530-1
Organization: Individual
Commenter: Dale Olson

I find it truly amazing that in the past when environmental rules were promulgated EPA justifies them with health risks and estimates of deaths. In the case of fuel economy you are disregarding this very concern. To achieve high fuel economy standards vehicles will be made of lighter less strong materials which will make the vehicles less safe and significantly increase highway fatalities. I find it disingenuous that in this case human health can be discounted.

Comment Number: 0554-5
Organization: Individual
Commenter: James Adcock

NHTSA continues to misinterpret the results of Kahane exactly backwards. Kahane's studies illuminate nothing about how manufacturers might actually design new vehicles to achieve higher furl economy. For hypothetical example a vehicle redesigned to have a carbon fiber body with the same stiffness but lower weight might have higher fuel economy AND greater safety. We don't know. Nothing in the Kahane studies comes close to addressing these kinds of engineering design tradeoffs. But on the contrary, Kahane does well-model the scenario where in the face of high gas prices consumers are on average forced within an existing market mix of vehicles to purchase slightly smaller vehicles in order to achieve affordable fuel economy when facing a market where NHTSA and Manufacturers have failed to provide vehicles with fuel economy matching market gas prices. NHTSA then, should be looking to Kahane to illuminate the excess deaths caused to consumers when NHTSA sets fuel economy standards too weak in the face of high gas prices. Such a failure to regulate, and the excess deaths that result, represent a direct failure of NHTSA to meet its primary mandate of Highway Safety. Weak fuel economy standards equals excess traffic deaths. Not the other way around. Consumers need to be able to buy the fuel economy they need in the vehicle size they want without being forced to downsize due to NHTSA setting fuel economy standards that are too weak. Continuing to read Kahane "backwards" results in setting GHG emissions standards too high.

Comment Number: 0572-63
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The NPRM, on page 24359, states that a 2002 report by a committee of the National Academy of Sciences "cautioned that the safety effects of downsizing and downweighting are likely to be hidden by the generally increasing safety of the light-duty vehicle fleet. It said that some might argue that this improving safety picture means that there is room to improve fuel economy without adverse safety consequences; however, such an approach would not achieve the goal of avoiding the adverse safety consequences of fuel economy increases." However, this misrepresents the findings of the report by omitting the findings that weight reduction for vehicles greater than 4,000 lbs. curb weight would result in a safety benefit, as was discussed in detail in the recent Ninth Circuit opinion. [Footnote: See original comment document.] Omitting the benefits of weight reduction skewed the development of the CAFE standards toward lower efficiency vehicles.

Comment Number: 0576-32
Organization: Public Citizen
Commenter: Joan Claybrook

NHTSA's unfounded position on weight reduction reinforces the common myth that fuel economy standards reduce vehicle safety by promoting downweighting. The agency says directly in its notice "[b]ecause downweighting is a common compliance strategy, and because the agency believes that downweighting of lighter vehicles makes them less safe, our model does not rely on weight reductions to achieve the standards for vehicles under 5,000 pounds GVWR and then only up to 5 percent." Downweighting of lighter vehicles has actually never been a common compliance strategy. When NHTSA implemented its first fuel economy standards in the 1980s, 85 percent of fuel economy gains were made by adding fuel saving technologies, and only 15 percent came from weight reductions, and then weight was only removed from the heaviest vehicles. [Footnote: See original comment document.]

NHTSA relies on a 2003 study by Charles Kahane to justify not considering weight reduction as a compliance strategy for vehicles under 5,000 pounds GVWR (73 FR 24456.) Kahane's study oversimplifies the relationship between weight and safety, obfuscates findings which show that reducing weight from only the *heaviest* vehicles actually improves safety, and overlooks the relationship between the *difference* in vehicle weight, rather than simply the weight of the vehicle. [Footnote: See original comment document.] NHTSA has taken the position that improving fuel economy by reducing vehicle weight poses an unconscionable threat to highway safety, largely based on the Kahane study and Crandall-Graham analysis cited above. [Footnote: See original comment document.] The auto industry opposes a focus on extensive weight reduction because pickup trucks and SUVs have been their cash cows.

One way of thinking about the impact of fuel economy and safety is in terms of compatibility and aggressivity of a given vehicle in a two-vehicle crash. "Compatibility" refers to how well one vehicle matches with another in a crash, and "aggressivity" roughly describes how harmful a vehicle is to occupants of a struck vehicle in a two-vehicle crash. [Footnote: See original comment document] There are several vehicle attributes which describe vehicle compatibility and aggressivity, such as weight, bumper overlap, vehicle geometry, including bumper height and average height of force, and front-end stiffness. (S. 357 of the 110th Congress, the "Ten in Ten Fuel Economy Act," introduced by Sen. Dianne Feinstein on January 22, 2007 included a provision which would have required NHTSA to establish a compatibility and aggressivity reduction safety standard to promote improved vehicle compatibility. While this language was not included in the Energy Independence and Security Act, Public Citizen recommends that NHTSA develop a compatibility and aggressivity standard.] NHTSA's position on fuel economy and safety is inconsistent with its own research on incompatibility.

The agency claims that the restructured CAFE scheme will improve safety by "eliminating the regulatory incentive to downsize vehicles." (71 FR 17568) But NHTSA ignores the impact that the light truck loophole has already had on safety through increased incompatibility, and fails to address the problem by providing no regulatory incentive for automakers to build more compatible light trucks, or by amending the regulatory definitions of cars and light trucks to close this dangerous and wasteful loophole. NHTSA says "by raising the light truck standards . . . there is no regulatory incentive from the CAFE program to design small vehicles as light trucks instead of passenger cars." This overlooks the fact that the new standards do not close the light truck loophole. It sets lower standards for larger vehicles, and eliminates the leveling effect of the corporate average (that is, balancing lighter vehicles against heavier ones). [Footnote: See original comment document]

Comment Number: 0600-11
Organization: Centers for Disease Control and Prevention
Commenter: Sarah Heaton, Andrew Dannenberg

The anticipated effects of increased CAFE standards on the human environment in the United States will occur primarily through the following mechanisms: 1) Fleet emission changes 2) Fuel consumption changes 3) Fleet design changes. To adequately assess the potential impact of CAFE standards on the human environment:

Health impact analysis and modeling of each mechanism is necessary for each of the proposed alternatives.

…Vehicle safety is a public health concern. Appropriate vehicle design as well as decreasing vehicle fleet disparities in size and weight can act to decrease crash-related injury to those driving lighter-weight automobiles and trucks as well as other modes of transportation such as bicycles, motorcycles, and scooters. Changing CAFE standards will affect fleet design and therefore have the potential to increase or decrease crash-related injury. Potential fleet design and composition by which vehicle manufacturers will comply with new CAFE standards warrants comprehensive analysis. Modeling these projections is critical to an adequate analysis of the impact that new CAFE standards will have on the human environment. To adequately promote and protect human health assuming shifts in the U.S. automobile fleet make-up:

Analysis of current vehicle fleet composition, prospective fleet composition, and optimal fleet composition with respect to transportation user needs, CAFE standards, and decreasing crash-related injury to transportation system users is also warranted for adequate assessment.

Response

NHTSA considered the potential safety concerns of making vehicles lighter (i.e., downweighting) in both the rulemaking and the FEIS. See DEIS Section 3.5.4, Safety and Other Human Health Impacts, for NHTSA's approach to these safety concerns. In that section, NHTSA describes the importance of the new form of the CAFE standard ("Reformed CAFE") to alleviate the potential for downweighting. By using an attribute-based standard, which the NAS recommended in 2002 and the EISA requires, NHTSA believes that the incentive to downweight vehicles should be reduced or eliminated.

Contrary to Public Citizen's concerns that NHTSA relies too heavily on the Kahane study, NHTSA routinely reviews the full spectrum of relevant studies because safety is a major NHTSA concern. Several of these studies are noted in the FEIS. See Section 3.5.4.

It is because of this complexity that NHTSA believes that all relevant literature should be examined. Public Citizen cites the dissent to the NAS study, but fails to note that the majority report, agreed to by 11 of 13 panel members, concluded that downsizing and weight reduction that occurred in the late 1970s and early 1980s likely resulted in between 1,300 and 2,600 crash fatalities under the previous form of the CAFE standard. This led to the NAS recommendation that the form of the CAFE standards be changed to an attribute-based approach. As for misinterpreting the results of the Kahane study, as Mr. Adcock alleges, Dr. Kahane is on the NHTSA staff and is a recognized expert in the field of vehicle safety. His interpretation of the results of his own study is definitive.

While the study of safety and fuel economy is multi-faceted, Public Citizen's recommendation for compatability and agressivity standards is misplaced. NHTSA can use its authority under the Safety Act to address unreasonable risks to safety. NHTSA's rulemaking and its EIS are focused directly on new CAFE standards. The FEIS addresses safety concerns because they are potential health impacts.

NHTSA agrees with CDC's statement that changing fleet design can have important impacts on human health, but disagrees with CDC's contention that prospective vehicle fleets, or an "optimal" vehicle fleet, can be assessed for impacts on human health. One of NHTSA's primary responsibilities is to assess the crashworthiness of current model vehicles, a responsibility we faithfully fulfill. CDC's proposed analysis, on the other hand, would go far beyond this, and demonstrates a lack of understanding regarding the structure of the rulemaking. NHTSA has no authority to require a specific composition of the vehicle fleet. This proposed rulemaking does not require vehicle manufacturers to implement specific technologies or specific approaches to meet the new standards. Manufacturers might or might not meet their requirements by downweighting (against NHTSA's advice for most vehicles). There is a wide variety of technologies available to assist manufacturers to comply with the new standards. The extent to which they will do so in reaction to the new standards cannot be accurately estimated. Therefore, NHTSA concludes that the analysis CDC proposes would be impossible to do in any sort of a meaningful way.

10.3.6.5 Hazardous Materials and Regulated Wastes

Comment

Comment Number: 0595-7
Organization: Environmental Protection Agency
Commenter: Susan Bromm

EPA believes the DEIS could be strengthened (page 3-88) by adding supporting information on the topic of hazardous materials. We recommend the DEIS document in more detail that future efforts at downweighting of vehicles by substitution of aluminum, plastics, composites, and synthetic materials for steel and ductile iron parts, will not result in a net (overall) increase in the hazardous waste stream, and that if there are any increases, these will be manageable under current technologies.

Some published studies have also suggested that the trend toward substitution of lighter weight aluminum for steel in autos increases energy demands and may result in increased pollution from bauxite mining, alumina refining, and aluminum smelting operations. The DEIS should cite current research on how the substitution of lighter weight materials can avoid significant effects on water or biological resources, and reduce CO_2. The DEIS simply states that the "projected reduction in fuel production and consumption as a result of the proposed action and alternatives may lead to a reduction in the amount of hazardous materials and wastes created by the oil extraction and refining industries." No mention is made of the consequences/impacts of the increasing substitution to lighter weight materials.

Response

NHTSA has revised Section 3.5.5 to include a discussion of the hazardous-waste stream and lighter materials.

10.3.6.6 Environmental Justice

Comment

Comment Number: TRANS-15-1
Organization: Individual
Commenter: Marissa Knodel

This is an issue of environmental justice, since these countries have contributed the least to global warming, and yet given their size, location, geography and lack of political power, will suffer the most from global warming.

The highest point on many of these islands is only a few years high. Now, with global warming causing sea levels to rise, and increasing the magnitude and severity of tropical storms, many of these nations already have agreements with the governments of New Zealand and Australia to evacuate their entire populations with the expectation that their homes will be under water within the next 50 years.

Response

Sections 4.5 and 4.6 of the FEIS include discussions of the effects of climate change on environmental justice populations; these sections describe the particular vulnerability of low-lying atolls to sea-level rise. NHTSA recognizes that populations on low-lying atolls are likely to be disproportionately affected by sea-level rise as a result of increased CO_2 emissions. However, these impacts are from global emissions releases, not just from U.S. emissions releases. To the extent that the reductions estimated from the alternatives considered in this rulemaking reduce or delay sea-level rise, this rule could offset these impacts. However, to avert sea-level rise that would displace these populations, many more CO_2-reduction initiatives will be required.

10.3.7 Cumulative Impacts - General

Comment

Comment Number: TRANS-32-2
Organization: Environmental Defense Fund
Commenter: James Keck

We believe that NHTSA has failed to comply with the Ninth Circuit's previous mandate to quote, provide the necessary contextual information about the cumulative and incremental environmental impacts of the final rule in light of other CAFE rulemakings and other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes such other actions.

Response

NHTSA acknowledges that under NEPA we are required to take a "hard look" at the effects of our actions on global warming within the context of other actions that also affect global warming. Thus, consistent with CEQ regulations, guidance, and applicable case law, the DEIS and this FEIS provide appropriate contextual information about the cumulative impacts of increased CAFE standards "on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other actions." 40 CFR § 1508.7.

Agencies retain substantial discretion as to the extent of the inquiry and the appropriate level of explanation. Marsh v. Oregon Natural Resources Council, 490 U.S. 360, 376-77 (1989). Indeed, CEQ recognizes the impracticality of requiring an agency to "analyze how the cumulative effects of an action interact with the universe; the analysis of environmental effects must focus on the aggregate effects of past, present, and reasonably foreseeable future actions that are truly meaningful" (CEQ 2005). An EIS must discuss "reasonably" foreseeable cumulative effects. Blue Mountain Biodiversity Project v. Blackwood, 161 F.3d 1208, 1214-15 (9th Cir. 1998). When an agency's determination of "reasonably foreseeable future actions" and "component parts" is "'fully informed and well-considered,'" the courts will defer to the agency's determination. Id. at 1208 (quoting Save the Yaak Comm. v. Block, 840 F.2d 714, 717 (9th Cir. 1988)). Some level of detail is required in describing the cumulative effects of a proposed action. "To consider cumulative effects, some quantified or detailed information is required." Neighbors of Cuddy Mountain v. U.S. Forest Service, 137 F.3d 1372, 1376 (9th Cir. 1998).

The past and present actions related to the CAFE rulemakings are addressed in the emissions time series, as described in Section 4.4 of the FEIS. Although literally hundreds of future actions are contemplated to address climate change – both in the United States and elsewhere – the set of reasonably foreseeable actions is quite limited. In fact, existing regulatory commitments in the United States and elsewhere generally expire within the next 5 years (during the time the MY 2011-2015 CAFE standards would be in effect).

Although it is not possible to reasonably foresee the profile of global GHG mitigation policies over the remainder of the 21st Century, the SRES emissions scenarios NHTSA used in the climate modeling bracket a wide range of potential combinations of population, economic development, technology evolution, and energy intensity. While they are not designed to portray various GHG mitigation policy outcomes, they indicate the effect of a diverse set of conditions. NHTSA has expanded the FEIS analysis to use multiple emissions scenarios and multiple climate sensitivities, which provide insight on how the regulatory options affect climate under a variety of background conditions. See Section 3.4.4.4.

10.4 OTHER COMMENTS ON THE DEIS

10.4.1 Mitigation

Comments

Comment Number: 0572-28
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

After summarizing an environmental problem, the next required task of an EIS is to discuss ways to reduce the project's impact and solve the problem. This rulemaking is particularly well suited for such an analysis since EPCA requires the fuel economy standard to be set at the "maximum feasible" level and higher fuel economy standards result in lower greenhouse gas emissions. Yet the failure to discuss solutions is one of the DEIS's most glaring failures.

In the bizarre and constrained world presented in the DEIS, there is no solution to global warming. The full range of alternatives considered by NHTSA, combined with NHTSA's assumptions, discussed below, result in atmospheric CO_2 concentrations of between 705.4 and 708.6 ppm. DEIS at 2-16. While global warming is indeed a daunting problem, presenting the analysis in this truncated form leaves the false impression that nothing can be done about it, violating both the letter and the spirit of NEPA. Leading scientists are able to tell us with a high degree of certainty that allowing CO_2 concentrations to rise to more than 700 ppm by the end of this century will result in catastrophic climate impacts. NHTSA has a mandatory duty to disclose in the DEIS what NHTSA can do to contribute to the solution.

Comment Number: 0600-1
Organization: Centers for Disease Control and Prevention
Commenter: Sarah Heaton

Mitigation analysis for projected public health outcomes is necessary. Current mitigation analysis in the DEIS is insufficient.

Response

The commenters appear to misconstrue NEPA requirements and NHTSA's role in setting CAFE standards within the context of climate change. Climate change is global in nature and stems from GHG emissions that trap heat and cause global temperatures to rise. According to the IPCC and USCCSP, the final impacts of climate change are anticipated to include a wide variety of detrimental effects. The sources for these GHGs, however, are numerous. In addition to transportation sources, GHG emissions are generated by the industrial, commercial, agriculture, and residential sectors, and electricity generation. In fact, many human activities that require power generate GHGs because a great deal of our power is generated through the use of carbon-based fuels, including home heating and cooling, and driving. According to EPA's "Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2005" (2007d), Table 2-14, transportation sources (including air travel and freight) accounted for 28 percent of GHGs (expressed in carbon dioxide equivalents), and electricity generation accounted for 34 percent. Other sectors contribute to GHG emissions as follows: industry (19 percent), agriculture (8 percent), commerce (6 percent), and residential (5 percent).

To slow or reverse the anticipated impacts of climate change, it is likely that all sectors would have to reduce emissions. Some scientists have called for as much as an 80 percent reduction in GHGs *by 2050 to moderate (but not eliminate) the detrimental impacts of climate change. This will require substantial reductions from all sectors. Further, it will require such sectoral reductions in all nations.*

By contrast, NEPA only requires that NHTSA disclose the environmental impacts of its proposed action. NHTSA's action is limited to the CAFE rulemaking. EPCA, as amended by EISA, is not designed, and NHTSA has no authority, to dictate the U.S. Government's GHG emissions reduction policy. Addressing climate change in a meaningful way would likely require new legislation from Congress in conjunction with that from other nations.

The agency's action would result in substantial reductions in GHG emissions from passenger cars and light trucks in the United States, which, when considered in a global context, would result in small changes in temperature, precipitation, and sea-level rise. Under NEPA, this is the action NHTSA must evaluate for environmental impacts. Because the alternatives will reduce GHGs, the agency's action is expected to reduce the effects of climate change.

In addition, most of the air pollution emissions are anticipated to decrease, even as some increase slightly under some alternatives and in some years. The additional health analyses shown in Sections 3.3 and 4.3 indicate that net health impacts should be beneficial to human health. For these reasons, NHTSA continues to believe that mitigation, when considered within the NEPA definition of reducing the harmful effects of an agency's action, is unnecessary.

10.4.2 List of Preparers

Comments

Comment Number: 0596-1
Organization: Environmental Defense Fund
Commenter: Martha Roberts

Although the team that created this EIS is well-credentialed in many areas of environmental assessment, we do not believe they had the proper expertise to adequately evaluate the health impacts of the proposed CAFE alternatives. We note that among the team of 47 technical experts, the reviewers, and the project managers not one had obtained a graduate degree in public health. The National Highway Traffic Safety Administration (NHTSA) asserts in its response to comments from the Centers for Disease Control and Prevention (CDC) also calling for inclusion of public health professionals,

"NHTSA feels confident that the consultants retained to assist in the analysis and development of the DEIS, along with its own staff, have the requisite knowledge and skills to effectively incorporate health issues into the document." [Footnote: See original comment document.]

EDF supports the CDC's recommendation for inclusion of public health professionals in the process of developing the EIS. Given the length and complexity of this EIS, it is unlikely that a teleconference with the CDC was sufficient to obtain the "high degree of understanding" NHTSA asserts, and therefore unlikely that the appropriate disciplinary expertise in public health was applied to this EIS. [Footnote: See original comment document.]

Comment Number: 0600-12
Organization: Centers for Disease Control and Prevention
Commenter: Sarah Heaton

Collaboration with public health economists is warranted.

Response

NHTSA is confident that the consultants retained to assist in the analysis and development of this NEPA analysis, along with its own staff, have the requisite knowledge and skills to effectively incorporate health issues into the document. In addition, staff with degrees in public health have contributed to the analysis presented in the FEIS. See Chapter 7, Preparers.

10.4.3 Appendix C Cost-Benefit Analysis Excerpt from the Preliminary Regulatory Impact Analysis

Comments

Comment Number: 0574-15
Organization: Alliance of Automobile Manufacturers
Commenter: Julie Becker

The technology penetration tables in the PRIA are not sufficient to show the technology combinations that NHTSA actually assumed. The information contained in the "decision tree" figures isn't sufficient either. Answers to the following questions would help us determine what combinations were actually modeled:

1. Why does the MY 2015 penetration rate of VVT [variable valve timing] technology in Table V-11b and similar tables exceed 100%?

2. On which transmissions is ASL [aggressive shift logic] assumed to be used in MY2015?

3. What other engine technologies are used in combination with Turbo/Downsize? Specifically, is VVLTD [variable valve lift and timing (discrete VVL)], VVLTC [variable valve lift and timing (continuous VVL)], or cylinder deactivation (DISP) assumed?

4. In the "decision tree" on page V-64, is DISP retained when VVLT is added?

5. In the "decision tree" on page V-64, is VVLT retained when GDI [gasoline direct injection] is added?

6. In the "decision tree" on page V-65, is ASL retained when the transmission is changed to AMT [Automated Shift Manual Transmission]?

Answers to the following questions would help clarify the benefit estimates that NHTSA is assuming for specific technologies:

1. Shift Logic — Does NHTSA have a specific definition of baseline non-aggressive shift logic and aggressive shift logic in terms of the upshift and downshift points as a function of engine load in each gear? How did NHTSA determine the percent of vehicles using aggressive shift logic in the baseline?

2. Understanding Hybrid Benefits — Based on Table V-2, the benefits of 2-mode hybrids and Power Split hybrids over the non-hybrid baseline are 15.2% (1-(1.075*1.035*1.035)) and 22.6% (1-(1.075*1.035*1.035*1.065)), respectively. However, the text says "NHTSA estimates that Power Split hybrids can achieve incremental fuel consumption reductions of 25 to 35% over conventionally powered vehicles." Is the difference due to the fact that the hybrid estimates in

Table V-2 are incremental to the use of something other than "conventionally powered vehicles?" If so, at what point in the "decision trees" are hybrids applied and do the engine technologies already applied at that point carry forward? For example, is hybrid technology used in combination with Turbo/Downsize or VVLTC? Is it correct to assume the transmission technologies do NOT carry forward, but the hybrid benefits are incremental to something other than a baseline transmission? If so, what is the transmission that the hybrid system benefits are incremental to?

3. Cam Phasers — The decision tree on page V-64 indicates that dual cam phasers are applied subsequent to the use of intake cam phasers. Does that mean that the benefit of dual cam phasers shown in Table V-2 is incremental to intake cam phasing?

4. In Table V-2, is the benefit for cylinder deactivation incremental to the use of dual cam phasers and are dual cam phasers assumed to still be used?

5. In Table V-2, are the benefits for VVLT incremental to cylinder deactivation and is cylinder deactivation assumed to still be used when VVLT is added?

6. On the overhead valve branch of Table V-2, does the incremental benefit for continuous VVLT assume that coupled cam phasing was in the baseline?

7. If cylinder deactivation is ever assumed to be used in combination with VVT or VVLT, what "synergy" was assumed?

8. If cylinder deactivation or VVLT are ever assumed to be used in combination with Turbo/Downsize, what "synergies" are assumed?

Comment Number: 0595-27
Organization: Environmental Protection Agency
Commenter: Susan Bromm

The excerpted Cost and Benefit RIA chapters appear to have been pulled from an outdated version of the RIA. EPA recommends that the text be replaced with that found in the April, 2008 version of the RIA.

Response

To the extent that the AAM and EPA have identified aspects of NHTSA's analysis that need updating, clarifying, or correcting, NHTSA has revised its analysis. Other comments from AAM address very specific issues concerning the application of technologies to improve fuel economy in the Volpe model. NHTSA has taken all of the AAM's questions and suggestions regarding technology costs and transparency of analysis into consideration in revising and updating the technology inputs to the Volpe model. For further discussion of this issue, see the agency response in 10.2.2 above.

10.4.4 Additional Comments

Comments

Comment Number: 0554-11
Organization: Individual
Commenter: James Adcock

Manufacturers are widely misrepresenting EPA Fuel Economy values on TV by quoting highway mileage values as if they are combined mileage values. NHTSA needs to act to correct these deliberately distorting practices. These advertisements are in turn representative of the fact that NHTSA has been setting fuel economy standards too low, forcing manufacturers to misrepresent to the public how they have chosen to implement those standards. Allowing these advertising deceptions results in higher GHG.

Comment Number: 0575-10
Organization: Union of Concerned Scientists
Commenter: Eli Hopson

Based on Tables la and lb from the Preliminary Regulatory Impact Analysis, it appears that NHTSA expects a significant number of manufacturers will opt for civil penalties instead of compliance. Under NHTSA's proposed "Optimized (7%)" scenario, the projected harmonic average for the passenger car fleet falls 0.2-1.0 mpg (between 2011 and 2015) short of the required fleet average, while the projected harmonic average for the light truck fleet falls 0.2-0.6 mpg short of the required fleet average. [Footnote: See original comment document.] Under other scenarios (i.e., Optimized (3%), TC=TB, etc.) projected harmonic averages fall short of required fleet averages by even greater amounts.

The $5 penalty has remained in effect since 1975. Since that time, inflation has devalued the impact of that penalty. A fine of equivalent value today would need to be more than $20 per 0.1 mpg. [Footnote: See original comment document.] Increasing the noncompliance civil penalty would boost its effectiveness in achieving its original policy intent. Given the escalating economic and environmental importance of energy conservation, UCS [Union of Concerned Scientists] recommends that the Secretary of Transportation invoke a CAFE noncompliance civil penalty of $10 per 0.1 mpg.

Comment Number: 0575-30
Organization: Union of Concerned Scientists
Commenter: Eli Hopson

NHTSA's analysis indicates that a significant number of manufacturers will opt for civil penalties over compliance with fuel economy requirements. Increasing the civil penalty would ensure the benefits are actually realized. The Secretary of Transportation should use existing authority to increase the CAFE noncompliance civil penalty from $5 to $10 per 0.1 mpg.

Comment: Number: 0572-49
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

The NRPM on page 24461 further argues that "since EISA now permits manufacturers to transfer credits earned for their passenger car fleet to their light truck fleet and vice versa, it makes even less difference how a vehicle is classified, because the benefit a manufacturer gets for exceeding a standard may be applied anywhere." However, the NPRM on page 24393 states explicitly that NHTSA "does not attempt to account for either CAFE credits or over-compliance … EPCA and EISA do not allow NHTSA to consider those credits toward compliance in future or prior model years. Therefore, the Volpe model does not attempt to account for these flexibilities." Thus, NHTSA specifically constrained the Volpe model from including precisely those considerations that NHTSA points to as justification for not revising the definition of light trucks, indicating that the revision of the definitions to classify pickup trucks and SUVs as passenger vehicles would indeed result in higher standards for many vehicles.

Response

Fuel economy advertisements: The issue of whether any advertisements misrepresent EPA fuel economy estimates is beyond the purview of this action and, in any event, within the jurisdiction of the Federal Trade Commission.

Civil penalties: As discussed in the NPRM, EPCA authorizes NHTSA to increase the civil penalty up to $10.00 for each tenth of a mpg that a manufacturer's average fuel economy falls short of the standard for a given model year, exclusive of inflationary adjustments, if NHTSA decides that the increase in the penalty (1) will result in, or substantially further, substantial energy conservation in model years in which the increased penalty may be imposed, and (2) will not have a substantial deleterious impact on the economy of the United States, a State, or a region of a state. See 49 U.S.C. § 32912(c). In the NPRM, NHTSA asked for comments on whether it should initiate a proceeding to consider raising the civil penalty. A number of commenters indicated that they would favor raising the civil penalty to $10. NHTSA will consider the comments in deciding whether to initiate rulemaking to raise the civil penalty.

Credits: CBD's comment suggests that NHTSA might not have been completely clear in its explanation of how the use of credits interacts with the classification of vehicles. NHTSA does not believe that the statutory prohibition on considering credits in determining CAFE standards has the effect of producing standards that would be higher if NHTSA reclassified certain light trucks as passenger cars.

10.4.5 Rulemaking

10.4.5.1 State Preemption

Comments

Comment Number: 0554-4
Organization: Individual
Commenter: James Adcock

The NHTSA assertion of CAA [Clean Air Act] preemption is not rational for several reasons. First, NHTSA's proposed standards do not actually regulate GHG tailpipe emissions. Rather NHTSA sets relationships between tailpipe emissions and footprint. NHTSA does not know how much GHG will be emitted because it will depend on the actual mix of car, trucks, and their footprints. States might set rules that tend to affect this mix or limit GHG which would not stop NHTSA from setting whatever GHG/footprint, car versus truck relationships NHTSA wants. Secondly, Congress specifically prevents NHTSA from consideration of alternative fuels, which states might use in their regulations to limit overall GHG net emissions. For example California might set regulations designed to make 10% of their autos electric powered by green electricity, thereby reducing GHG emissions by 10% compared to federal regulations.

Comment Number: 0572-66
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

Following a rulemaking in which NHTSA repeatedly and systematically manipulates the analysis in order to select an absurdly low fuel economy level, NHTSA then asserts that its rulemaking preempts state regulation of greenhouse gas emissions from automobiles. NHTSA's statements in this regard are incorrect, inappropriate, and either legally irrelevant or contrary to existing law. We request that all statements regarding preemption be removed prior to publication of the final rule.

Comment Number: 0575-18
Organization: Union of Concerned Scientists
Commenter: Eli Hopson

UCS is disappointed in NHTSA's attempt to use this CAFE NPRM to address California's vehicle global warming pollution regulations. The previously discredited legal arguments made by the agency were rejected in decisions by the Supreme Court and two separate district courts. It is clear that EPA's authority to regulate greenhouse gases under the Clean Air Act is separate and distinct from NHTSA's authority to set fuel economy standards. It is inappropriate for NHTSA to go beyond its authority, challenge the court decisions, and parrot the auto industry's flawed legal claims. The administration should grant the waiver to California and allow the states to move forward.

Interestingly, as shown in Table 2 below [see comment document], NHTSA's own analysis demonstrates that with proper assumptions—such as employing a Total Cost-Total Benefit (TC=TB) economic practicability assessment, or using realistic gasoline prices—fuel economies higher than the approximate California Pavley regulation MPG equivalent are both technically achievable and economically practicable.

Response

NHTSA does not believe that the EIS is the appropriate forum in which to address the merits of NHTSA's position on preemption, and refers readers to Section XIII.D of the NPRM. While NHTSA has explained its considered view that state GHG emission regulations for motor vehicles are largely preempted by EPCA insofar as those regulations address tailpipe emissions of CO_2*, EPCA does not have any effect on state regulation of matters beyond NHTSA's authority (for example, GHGs from motor vehicles other than tailpipe emissions of carbon dioxide), or from motor vehicles (for example, motorcycles) or other machinery not subject to CAFE. NHTSA also has no authority over state regulation of alternative fuels, although it does have authority over state regulation of alternative-fuel vehicles, as such regulations would be "related to fuel economy" and preempted under 49 U.S.C. § 32919. In terms of the environmental impacts of such state regulations, however, NHTSA cannot analyze the effects of inchoate potential future regulations with any reasonable degree of certainty. NHTSA notes further that EPA denied California's Clean Air Act waiver request, as noted in the NPRM, and that California's (and other states' based on California's) light-duty motor vehicle GHG regulations are therefore currently unenforceable. NHTSA will address comments regarding the preemption issue in the final rule.*

10.4.5.2 Vehicle Footprint

Comments

Comment Number: 0554-3
Organization: Individual
Commenter: James Adcock

Truck CAFE curves cross Car CAFE curves. [See graph attached to original comment document.] For several years at medium values of footprint NHTSA compliance curves set lower values for cars than for trucks. Since the mpg values for trucks have historically been set lower than for cars because of the unique challenges and abilities trucks have, including greater hauling capacity and greater towing capacity, inverting this relationship never makes sense. This problem is part of a larger problem: that NHTSA has largely designed the curves for cars and trucks independently when instead NHTSA needs to recognize that both consumers and manufacturers have the choice of car versus truck. Thus the curves for cars and trucks need to be designed in a consistent and rational manner to work together. For example, the great disparity between car and truck curves for small footprints should encourage manufacturers to design “AMC Eagle” style small “trucks” which have car-like characteristics except for being high and needlessly unstable, leading to unnecessary rollover fatalities. NHTSA's choice of design curves for cars versus trucks works directly against NHTSA's charter of highway safety while resulting in greater GHG.

Comment Number: 0554-6
Organization: Individual
Commenter: James Adcock

Bias in the High Threshold transition point of the truck curves. NHTSA has lowered the high point threshold in the truck curves without a rational basis for doing so. Having incomplete information on the subject means choosing a best estimate, not biasing that estimate. Biasing this threshold results in greater GHG, and reduces most consumers’ ability to choose a rationally sized vehicle to meet their family’s needs without fear of death in collisions with those large trucks that the biased high threshold encourages, which again increases GHG.

Comment Number: 0575-17
Organization: Union of Concerned Scientists
Commenter: Eli Hopson

A size-based system has a built-in risk of vehicle upsizing whereby manufacturers upsize vehicles in order to achieve lower fuel economy targets. This issue is a less of a concern when the logistic curve is not as “steep.” As noted in the NPRM, however, the proposed curves, particularly those for passenger cars are quite steep, opening the door for manufacturer “gaming.” Under the proposed curves, for example, a Honda Civic could lower its target by almost 2 mpg (38.4 to 36.6) by simply increasing its footprint 1 square foot. Similarly, a 1 square foot change in size would lower the Saturn Aura’s target fuel economy by nearly 1 mpg. Vehicles have, indeed, been getting larger; the archetypal Honda Accord sedan’s footprint, for example, increased by 0.6 ft^2 between 2001 and 2004, and an additional 1.9 ft^2 by 2008. [Footnote: See original comment document.] Certainly, with such steep curves, ample opportunities exist for all manufacturers to game the system to their favor, eroding warranted energy savings.

UCS strongly opposes the adoption of a “dual attribute” approach, as it is unclear that a reasonable second attribute exists that will deliver the benefits of a size-based system. One unfortunate consequence of an attribute-based system is that the attribute is removed from the “toolkit” of resources automakers can employ to make their vehicles more fuel efficient. The incorporation of a second attribute, such as horsepower, would remove automakers' abilities to use the attribute to improve vehicle fuel economy. Worse yet, the attribute becomes a mechanism for the industry to "game" their fuel economy obligations; automakers could boost engine power to help a vehicle meet a lower fuel economy target. For the past 20+ years, automakers have steadily increased vehicle weight and power while keeping fuel economy constant. Today's average vehicle is 900 pounds heaver and has 90 percent more horsepower than its 20 year-old counterpart. [Footnote: See original comment document.] NHTSA should not employ regulations that further encourage this attribute trend.

Response

NHTSA uses the same methodology for setting both the passenger-car and light-truck curves, as discussed in the NPRM, but applies that methodology to the passenger-car and light-truck fleets separately, because EPCA (as amended by EISA) requires NHTSA to set separate standards for passenger cars and light trucks.

NHTSA explained at length in the NPRM that it is aware of steepness issues with the proposed passenger-car curve and has considered the issue very carefully in developing the FEIS and the final rule. The curves representing the analysis contained in this FEIS are much less steep than the curves in the NPRM. Regarding the concerns expressed by UCS about attribute-based CAFE standards, NHTSA notes that an attribute-based standard is required under EISA and was recommended by the National Academy of Sciences (NAS). NAS' expressed concern was the potential for downsizing and its negative impacts on safety. NHTSA notes the UCS concern, but it runs counter to the law and the NAS recommendation.

10.4.5.3 Ratably

Comments

Comment Number: TRANS-01-6
Organization: Alliance of Automobile Manufacturers
Commenter: Julie Becker

In our scoping comments, we asked NHTSA to consider how to construe the term ratably, a term that the Energy Dependence and Security Act of 2007 makes central. And so we would ask you to reconsider that issue as well.

Response

NHTSA disagrees that the EIS alternatives were not properly established because the agency did not conduct a full "textual" analysis in interpreting the term "ratably." NHTSA analyzed a range of alternatives that would capture a full spectrum of potential environmental impacts, ranging from vehicles continuing to maintain their MY 2010 fuel economy, to standards based on the maximum technology expected to be available over the period. The various alternatives analyzed create standards that present several points on a continuum of alternatives. A different construction of the term "ratably" than NHTSA used in the NPRM might affect the levels of increase in the standards from one year to the next, but we are satisfied that any "ratable" analysis would still fall within the spectrum covered by the existing alternatives and would have impacts that fall within the range identified in this FEIS. Therefore the decisionmakers and the public will be fully informed of the potential environmental impacts of all the reasonable alternatives.

10.4.5.4 Vehicle Classification

Comments

Comment Number: 0572-62
Organization: Center for Biological Diversity
Commenter: Brian Nowicki, Mickey Moritz, Kassie Siegel

In the development of the proposed CAFE standards, NHTSA relies on an outdated and inadequate definition of light trucks. This defies the recent Ninth Circuit opinion that found the use of these definitions to be arbitrary and capricious and required NHTSA to revise the definition of light trucks and, by extension, SUVs. [Footnote: See original comment document.] NHTSA's attempt to justify its failure to revise the definitions of light trucks and SUVs to reflect the fact that light trucks and SUVs are overwhelmingly used as passenger vehicles is unavailing. 73 Fed. Reg. 24459.

The NPRM on page 24460 argues that "The EISA adds a significant requirement to EPCA—the combined car and light-truck fleet must achieve at least 35 mpg in the 2020 model year. Thus, regardless of whether the entire fleet is classified as cars or light trucks, or any proportion of each, the result must still be a fleet performance of at least 35 mpg in 2020. This suggests that Congress did not want to spend additional time on the subject of whether vehicles are cars or light trucks." However, this interpretation entirely fails to address the primary reason for revising the definition of light truck—the fact that SUVs and pickup trucks are overwhelmingly used as passenger vehicles.

Comment Number: 0575-16
Organization: Union of Concerned Scientists
Commenter: Eli Hopson

The Energy Independence and Security Act of 2007 sets separate attribute-based target mpg levels for passenger and non-passenger vehicles, accommodating an industry interest in having non-passenger vehicles held to less stringent fuel economy standards than passenger vehicles of the same attribute (i.e., footprint size). These separate standards, which have been in effect in one form or another since the 1970s to accommodate performance-oriented, non-passenger work vehicles, are the source of a long-standing loophole created when NHTSA began equating SUVs, minivans, crossovers and even some station wagons with non-passenger vehicles. The association of these categories has allowed automakers to tweak passenger vehicle characteristics in order to have them classified as light trucks that are held to lower fuel economy standards.

This "gaming" of the system is contrary to the original intent of the law and robs the nation of energy savings. In a 2007 ruling on NHTSA's fuel economy standards for model year 2008-2011 light trucks, the Ninth Circuit Court of Appeals deemed that NHTSA's decision not to close the SUV loophole (by revising the definition of passenger and non-passenger automobiles) was arbitrary and capricious. The court ruled that, among other factors, NHTSA's decision "runs counter to the evidence showing that SUVs, vans, and pickup trucks are manufactured primarily for the purpose of transporting passengers and are generally not used for off-highway operation." [Footnote: See original comment document.]

In NPRM documentation, NHTSA argues that Congress had the opportunity to change the definitions and did not, which "strongly suggests Congressional approval of the agency's 30-year approach to vehicle classification." [Footnote: See original comment document.]

As the saying goes, absence of evidence is not evidence of absence. In not addressing the definitions legislatively, Congress merely preserved the same definitions upon which the Ninth Circuit decision was made. The notion that Congressional inaction "strongly suggests" approval is flawed. It could equally be interpreted that the inaction of Congress was a result of a belief that the Ninth Circuit decision (which came out a month before passage of the Energy bill) sufficiently spoke to the issue and negated a need for clarification. Indeed, in an extension of remarks on the Senate amendments to H.R. 6, bill author Congressman Edward I. Markey (D-MA) specifically noted,

"Section 1061 is not intended to codify, or otherwise support or reject, any standards applying before model year 2011, and is not intended to reverse, supersede, overrule, or in any way limit the November 15, 2007 decision of the U.S. Court of Appeals for the Ninth Circuit in *Center for Biological Diversity v. National Highway Traffic Safety Administration* (No. 06-71891)." [Footnote: See original comment document.]

Given these findings, UCS recommends that NHTSA revise its definition of passenger and non-passenger vehicles in accordance with the ruling of the Ninth Circuit Court of Appeals.

Comment Number: 0576-42
Organization: Public Citizen
Commenter: Joan Claybrook

Now that the market is shifting towards vehicles that more closely resemble large cars and station wagons, NHTSA should restore their classification as cars, primarily designed for the purpose of transporting passengers.

Response

Comments on the issue of classification may be grouped into several categories of arguments that the regulatory definitions relating to whether some vehicles are passenger cars or light trucks were incorrect: first, that they did not comport with the Ninth Circuit's opinion in CBD and do not reflect the fact that many light trucks are used as passenger vehicles; second, that they were not ratified by Congress in EISA; third, (which is related to the first) that they do not ensure that some vehicles which they believe should be classified as passenger cars are in fact classified as such; and fourth, they allow manufacturers to "game" the definitions by making minor changes to vehicles to obtain a light truck classification and thus, a lower fuel economy targets. NHTSA responds to these comments below.

In light of the Ninth Circuit remand, NHTSA intends to include certain vehicles in the passenger automobile category that had been in the light truck category. *As proposed in the NPRM, in this FEIS, NHTSA has tightened the coverage of its regulatory definition of "light truck" to ensure that two-wheel drive versions of an SUV are not classified as light trucks under 49 CFR § 523.5(b) simply because the SUV also comes in a four-wheel drive version. In order to be properly classifiable as a light truck under Part 523, a two-wheel drive SUV must either be over 6,000 lbs GVWR and meet 4 out of 5 ground clearance characteristics to make it off-highway capable under § 523.5(b), or it must meet one of the functional characteristics under § 523.5(a) (e.g., greater cargo carrying capacity than passenger carrying capacity). This clarification, which the vehicle manufacturers largely supported, would result in the re-classification of an average of 1,400,000 two-wheel drive SUVs from light trucks to passenger cars in each of the five model years covered by the standards. The result of this re-classification would be an average increase of 0.8 mpg in the combined passenger car and light truck standards over MY 2011-2015, producing a corresponding additional 4.5 billion gallons of fuel savings and 54 million metric tons of avoided carbon dioxide emissions during the useful life of vehicles sold during these model years. All of the alternatives and scenarios analyzed in this FEIS reflect this re-classification.*

As to other vehicles, NHTSA has considered in this FEIS whether recategorization would result in improved fuel economy and therefore lower emissions of carbon dioxide and other pollutants. This is discussed below.

NHTSA disagrees that consumers' use of vehicles is determinative of their CAFE classification. *With regard to the commenters' argument that the standards do not reflect the fact that many light trucks are used as passenger vehicles, NHTSA discussed at length in the NPRM that the fact that vehicles are used for personal transportation does not make them passenger cars for purposes of CAFE. The commenters' argument overlooks the statutory definition of passenger automobile. This term is defined to mean an automobile that the Secretary decides by regulation is "manufactured" primarily for transporting not more than . . ." The statute does not employ the word "used". If Congress had wanted all vehicles that transport passengers to be classified as passenger automobiles, it would have said "used primarily" in EPCA, instead of "manufactured primarily." The commenters also overlook the key role played by vehicle design and functional capabilities in vehicle classification for CAFE purposes. Instead, Congress specifically identified particular characteristics in the definition of passenger automobile, and gave NHTSA discretion to determine the contours of the regulatory definitions for purposes of the CAFE standards. NHTSA refers readers to the discussion in the NPRM at 73 FR 24458-24461 (May 2, 2008) for additional information on this issue. See further the discussion of EPCA's legislative history in the proposal and final rule establishing NHTSA's vehicle definition regulation. 41 FR 55368, 55369-55371, December 20, 1976, and 42FR 38362, 38365-38367, July 28, 1977. That discussion, and not the incorrect and anomalous description of it in a preliminary notice published by the agency in late 2003 (68 FR 74908, 74926, December 29, 2003), represents the agency's historical position.*

NHTSA disagrees that Congress intended to codify the Ninth Circuit opinion. *With regard to the commenters' argument that Congress did not approve of NHTSA's vehicle classification system in EISA and their suggestion that Congress codified the Ninth Circuit's opinion with respect to classification, NHTSA has carefully considered the discussion of this issue in the extension of remarks by Congressman Edward Markey. The agency notes that Congress did not amend the definition of "passenger automobile" or direct the agency to amend the definition of that term in the agency's classification regulation. NHTSA notes further that the remarks of Congressman Markey were not spoken on the floor during the House's consideration of EISA. 153 CONG. REC. H14253 (editor's note) and H14444 (daily ed. Dec. 6, 2007) (statement of Cong. Markey). Accordingly, we do not believe that the views in those remarks can be ascribed to Congress as a whole.*

In developing the EIS, NHTSA has considered whether changes in the regulatory vehicle categorization definitions in 49 CFR Part 523 would result in improved fuel economy and therefore lower emissions. *One of the concerns underlying the Ninth Circuit's decision was the potential impact of vehicle categorization on the ultimate fuel economy for light trucks. The commenters, too, were concerned about this in general. NHTSA has taken a hard look at this.*

In 2006, when NHTSA issued its MY 2008-2011 light truck fuel economy rule, and in 2007, when the Ninth Circuit issued its initial opinion in CBD, EISA had not been enacted. Under EPCA as it then existed, the passenger car standard was a flat 27.5 mpg average requirement. 49 U.S.C. 32902(b) Re-classifying light trucks as passenger cars, in the flat pre-EISA world, intuitively would have resulted in their having to meet a higher standard, or in the manufacturers' having to build more small, lightweight vehicles in order to balance out those new arrivals, and could have resulted in more fuel savings. This assumption may no longer be correct, because such a recategorization could now result in lower standards for passenger automobiles.

In EISA, Congress made both the passenger car and light truck standards attribute-based, which means that the fuel economy target curves for each standard are a function of the fleet subject to that standard. In developing the curves that determine fuel economy targets for each vehicle footprint, NHTSA fits the curve based in part on the sizes (footprint) and fuel economy levels (given the estimated effects of adding fuel-saving technologies) of the vehicles in each regulatory class. Consider, for example, a small SUV typically classified as a light truck, and assume that the small SUV gets relatively good fuel economy for a truck. Moving the small SUV out of the truck fleet may reduce the overall average fuel economy level required of light trucks, because the vehicles remaining that regulatory class will be the larger ones that have relatively lower fuel economy. Averaging their capabilities will result in a lower target than if the small SUV in question was remained in place. Moving the SUV into the passenger car fleet may either boost or lower the average fuel economy level required of passenger cars, depending on how the size and potential fuel economy of the given SUV compares to those of the vehicles that were already classified as passenger cars.

NHTSA's analysis indicates that the direction and magnitude of the net effects of vehicle re-classification depend on the composition of the fleet and the specific nature of the change in classification. As shown in Figure 10-1, assigning two-wheel drive SUVs and those vehicles that do not meet the third row requirement to the passenger car fleet would add to the passenger car fleet a set of vehicles (labeled "PC Formerly Classified as LT") with fuel economy levels that are generally (though not universally) in the same range as those of passenger cars of similar footprint. However, further reassigning to the passenger car fleet minivans and vehicles that <u>do</u> meet the third row requirement, as commenters appear to suggest, would add to the passenger car fleet a set of vehicles (labeled "LT Reassigned to PC under Alternative Definition") with fuel economy levels that are generally (though not universally) lower than those of passenger cars of similar footprint. Figure 10-2 shows how the composition of the light truck fleet is affected by such shifts. Reassigning either the smaller or larger group of vehicles to the passenger car fleet removes from the light truck fleet vehicles that are generally (though not universally) smaller and more efficient than the vehicles that remain in the light truck fleet.

As discussed above, in the context of the MY 2011-2015 passenger car and light truck standards, moving 1,400,000 two-wheel drive SUVs from the light truck to the passenger car fleet, as reflected in this FEIS, increases the fuel economy standards for both light trucks and passenger cars. However, going further and reclassifying other light trucks as passenger cars, as the commenters would have NHTSA do, would change the form and stringency of the curves for the maximum feasible standards. Substantially, it would reduce overall average required CAFE levels by an average of 0.4 mpg during MY 2011-2015, reducing fuel savings by 2.7 billion gallons over the useful life of vehicles sold in these model years, and increasing carbon dioxide emissions by 28 million metric tons.

Accordingly, EPCA and EISA's overarching purpose of energy conservation would not be better fulfilled by further changing the vehicle classifications.

The current definitions are tighter and more difficult to game than commenters suggest. *With regard to the commenters' argument that the standards allow manufacturers to "game" the definitions by making minor changes to vehicles to obtain a light truck classification and thus, a lower fuel economy target, NHTSA notes that minor changes are not sufficient, and that fairly major changes would be necessary in order to reclassify a passenger car as a light truck. To make a two-wheel drive SUV a light truck, for example, manufacturers would need either to add a third row of seats to it, convert it to four-wheel drive, or raise its GVWR over 6,000 lbs and ensure that it met 4 out of the 5 ground clearance characteristics. These changes are not minor, and likely can be made only every several years at the time of one of the periodic vehicle redesigns. Additionally, the minor benefit to be gained in terms of a lower target must be balanced against consumer demand. In a time of high gas prices and increasing*

Figure 10-1. Passenger Car Fleet

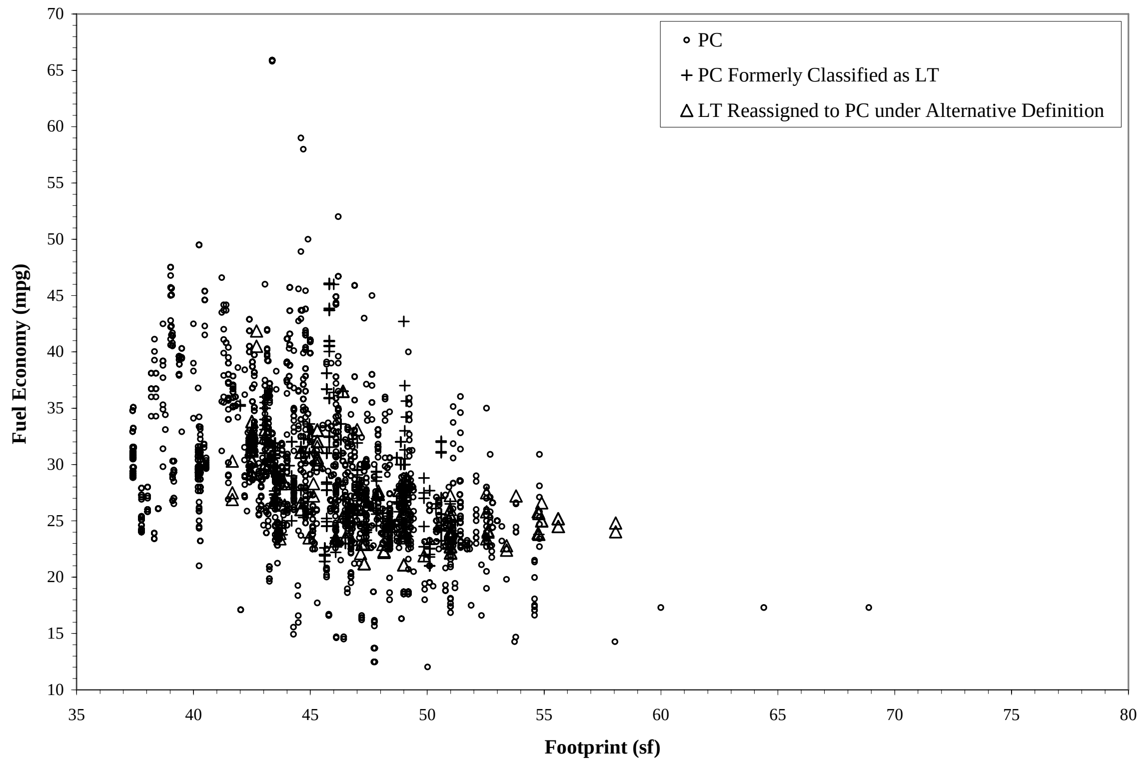

Figure 10-2. Light Truck Fleet

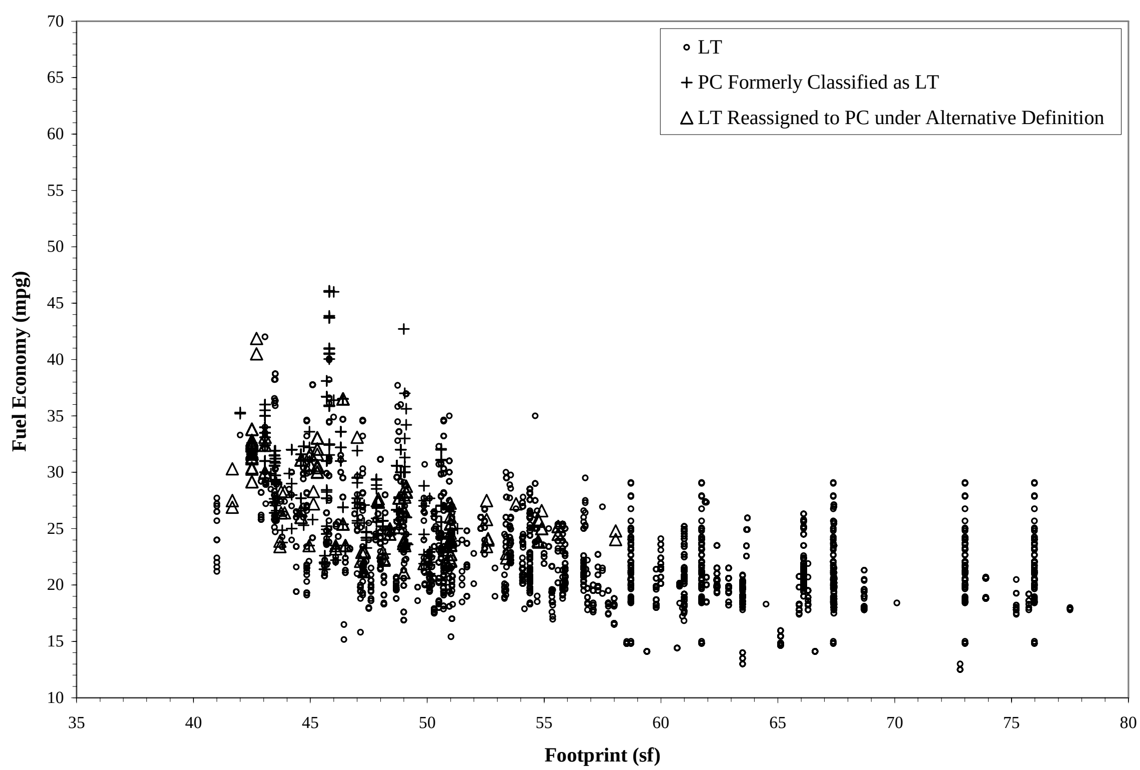

consumer interest in high fuel economy vehicles, it seems unlikely to NHTSA that manufacturers would take the risk of turning passenger cars into light trucks solely to obtain the slightly lower light truck target.

Further, to the extent that commenters and the Ninth Circuit believe that EPA's regulatory definitions for emissions purposes are "tighter" than NHTSA's, we note that this is not an apt comparison for several reasons. First, the NAS Report and the 9th Circuit are referring to EPA's Tier 2 criteria pollutant emissions requirements for mobile sources. These requirements are different from the CAFE requirements—light trucks produce more criteria pollutants than passenger cars not just because they tend to consume more fuel, but because their engines tend to be tuned differently to produce more torque for cargo-carrying and towing, which creates more pollution. Thus, the effect of having more light trucks on the roads (and thus wanting to limit their classification as light trucks) is greater for criteria pollutant emissions purposes than for CAFE purposes.

Second, EPA continues to use the same definitions as NHTSA does for CAFE purposes.[25] Even though EPA has changed its definitions for Tier 2 purposes, the effect of those changes was to move only four vehicle models—the Chrysler PT Cruiser, the Chevrolet HHR, the Honda Element, and the Dodge Magnum—whose combined production is currently less than 250,000 per year. NHTSA believes that manufacturers currently classify these four vehicles as light trucks either because they come in four-wheel drive, or because their rear seats may be easily removed to create a flat, floor level surface that increases cargo-carrying capacity. After MY 2011, vehicles may only be classified as light trucks on the basis of permitting expanded use of the vehicle for cargo-carrying purposes if they have three rows that fold flat. As currently designed, none of these four models would meet this requirement, so NHTSA would likely classify these vehicles as passenger cars as well. And third, after MY 2009, EPA will have no distinction between passenger cars and light trucks for Tier 2 purposes—all vehicles will be subject to the same standard. The fact that EPA has slightly restricted the definition of light truck for Tier 2 purposes will soon be entirely irrelevant.

In summary, EPA's "tightening" of the light truck category in Tier 2 resulted in the reclassification of less than 20 percent of the number of vehicles reclassified as a result of our tightening the implementation of our vehicle definitions. Further, EPA's action has little relevance to vehicle classification for CAFE purposes. This is proved by the fact that EPA ultimately intends to do away with the distinction between passenger car requirements and light truck requirements in Tier 2, an option which EPCA would not permit NHTSA to implement for CAFE.

With regard to commenters' argument that the existing definitions do not ensure that "vehicles that more closely resemble large cars and station wagons" (which NHTSA takes to refer to crossovers) are classified as passenger cars, we note that as a result of the tightened implementation of our vehicle definitions, many crossovers are in fact now properly classified as passenger cars. To the extent that crossovers are not classified as passenger cars, it is, we believe, only because they either (1) have four-wheel drive and meet 4 out of 5 ground clearance characteristics; (2) are over 6,000 lbs GVWR and meet 4 out of 5 ground clearance characteristics; or (3) have three rows of seats.

APPENDIX B

Energy, Air Quality, and Climate Modeling Data

Appendix B-1

ENERGY MODELING DATA

This appendix accompanies Sections 3.2 and 4.2 of the Final Environmental Impact Statement (FEIS) and presents fuel consumption results from two additional scenarios that NHTSA ran in the Volpe model. As is the case with Reference Case and High Scenario results presented in Sections 3.2 and 4.2, fuel consumption in the Mid-1 and Mid-2 Scenarios encompasses both gasoline and diesel. Like the High Scenario, the Mid-1 and Mid-2 Scenarios use the fuel prices drawn from the High Price Case in the AEO 2008. Results from the Mid-1 and Mid-2 Scenarios fall between those from the Reference Case and High Scenario. Tables B1-1 through B1-4 correspond to Section 3.2 and show the direct effects on fuel consumption of proposed CAFE standards. Tables B1-5 through B1-8 correspond to Section 4.2 and show the cumulative fuel consumption of the vehicle fleet from the onset of the proposed standards.

Table B1-1

Mid-1 Scenario Passenger Car Annual Fuel Consumption and Fuel Savings (billion gallons)

	Alternative CAFE Standards for Model Years 2011-2015						
	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5	Alt. 6	Alt. 7
Calendar Year	No Action	25% Below Optimized	Optimized	25% Above Optimized	50% Above Optimized	Total Cost Equal Total Benefit	Technology Exhaustion

Appendix B-2

AIR QUALITY MODELING DATA

This appendix accompanies Sections 3.3 and 4.3 of the Final Environmental Impact Statement (FEIS) and presents the results of the air quality analysis for individual nonattainment areas. Each table provides the estimated reduction in emissions for one pollutant and calendar year of analysis for each nonattainment area by alternative. In each table, the emissions changes are presented for the proposed model year (MY) 2011-2015 CAFE Standards, and also for the cumulative impacts of the proposed MY 2011-2015 standards and the reasonably foreseeable MY 2016-2020 standards. The tables for the Reference Case are presented first, and then the tables for the High Scenario. Following these tables, national-level emissions results for the Mid-1 and Mid-2 Scenarios are presented.

Table B2-1

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.

b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.

c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)

EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.

b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.

c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)

EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.

b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.

c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)

EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

a/ Reductions are shown as negative values. Positive values are emission increases. Values of less than 0.005 tons/year are rounded to zero.
b/ Pollutants for which the area is designated nonattainment or maintenance as of 2008. Source: 40 CFR 81.
c/ Emissions thresholds in tons/year of: VOCs or NOx in ozone NAAs; primary PM2.5 in PM2.5 NAAs. Source: 40 CFR 51.853. These thresholds are provided for information only; a general conformity determination is not required for the proposed actions. (See section 3.3.1.)
EPA. 2008. Greenbook. Currently Designated Nonattainment Areas for All Criteria Pollutants. U.S. Environmental Protection Agency. http://www.epa.gov/air/oaqps/greenbk/ancl3.html. Accessed June 12, 2008.

Work Loss Days							
2015	0	-4,786	-6,286	-6,869	-7,214	-9,579	-18,055
2020	0	-16,252	-18,887	-20,226	-20,632	-25,842	-49,452
2025	0	-25,777	-29,269	-31,195	-31,616	-38,995	-74,497
2035	0	-36,751	-41,123	-43,781	-44,239	-54,224	-105,514

a/ Changes in health outcome for the No Action Alternative are shown as zero because the No Action Alternative is the baseline to which the emissions for the other alternatives are compared.
b/ Negative changes indicate reductions; positive emissions changes are increases.

Table B2-90

Mid-1 Scenario Alternative CAFE Standards
Nationwide Changes in Health Costs from Criteria Pollutant Emissions
from Passenger Cars and Light Trucks (US million dollars/year)

	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5	Alt. 6	Alt. 7
Year	No Action	25% Below Optimized	Optimized	25% Above Optimized	50% Above Optimized	Total Costs Equal Total Benefits	Technology Exhaustion
2015	0 a/	-44 b/	-54	-66	-77	-98	-223
2020	0	-219	-250	-292	-320	-409	-990
2025	0	-375	-416	-485	-524	-694	-1,808
2035	0	-580	-628	-730	-775	-1,074	-2,985

a/ Changes for the No Action Alternative are shown as zero because the No Action Alternative is the baseline to which the emissions for the other alternatives are compared.
b/ Negative changes indicate economic benefit; positive emissions changes are economic costs.

Chronic Bronchitis							
2015	0	-23	-31	-34	-35	-47	-88
2020	0	-130	-146	-152	-154	-182	-261
2025	0	-258	-283	-292	-292	-335	-408
2035	0	-421	-458	-470	-467	-528	-593
Emergency Room Visits for Asthma							
2015	0	-6	-7	-8	-8	-11	-21
2020	0	-31	-35	-37	-37	-44	-63
2025	0	-62	-68	-70	-70	-80	-98
2035	0	-101	-110	-113	-112	-127	-142
Work Loss Days							
2015	0	-4,804	-6,305	-6,889	-7,235	-9,601	-18,070
2020	0	-26,583	-29,884	-31,209	-31,481	-37,220	-53,440
2025	0	-52,861	-58,086	-59,891	-59,835	-68,617	-83,728
2035	0	-86,346	-93,877	-96,257	-95,754	-108,319	-121,611

a/ Changes in health outcome for the No Action Alternative are shown as zero because the No Action Alternative is the baseline to which the emissions for the other alternatives are compared.
b/ Negative changes indicate reductions; positive emissions changes are increases.

Table B2-92

Mid-1 Scenario Alternative CAFE Standards
Nationwide Changes in Health Costs from Criteria Air Pollutant Emissions from Passenger Cars and Light Trucks – Cumulative Effects with MY 2011-2015 Standards and Potential MY 2016-2020 Standards (US million dollars/year)

	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5	Alt. 6	Alt. 7
Year	No Action	25% Below Optimized	Optimized	25% Above Optimized	50% Above Optimized	Total Costs Equal Total Benefits	Technology Exhaustion
2015	0 a/	-44 b/	-54	-66	-77	-98	-223
2020	0	-355	-395	-438	-468	-564	-1,079
2025	0	-729	-793	-867	-908	-1,105	-2,019
2035	0	-1,210	-1,300	-1,415	-1,463	-1,838	-3,322

a/ Changes for the No Action Alternative are shown as zero because the No Action Alternative is the baseline to which the emissions for the other alternatives are compared.
b/ Negative changes indicate economic benefit; positive emissions changes are economic costs.

Table B2-93

a/ Emissions changes for the No Action Alternative are shown as zero because the No Action Alternative is the baseline to which the emissions for the other alternatives are compared.

b/ Negative emissions changes indicate reductions; positive emissions changes are increases.

c/ Data on upstream emissions reductions were not available for acrolein. Thus, the emissions for acrolein reflect only the change in tailpipe emissions.

a/ Emissions changes for the No Action Alternative are shown as zero because the No Action Alternative is the baseline to which the emissions for the other alternatives are compared.

b/ Negative emissions changes indicate reductions; positive emissions changes are increases.

c/ Data on upstream emissions reductions were not available for acrolein. Thus, the emissions for acrolein reflect only the change in tailpipe emissions.

2035	0	-62	-64	44	73	328	3,587

a/ Emissions changes for the No Action Alternative are shown as zero because the No Action Alternative is the baseline to which the emissions for the other alternatives are compared.

b/ Negative emissions changes indicate reductions; positive emissions changes are increases.

c/ Data on upstream emissions reductions were not available for acrolein. Thus, the emissions for acrolein reflect only the change in tailpipe emissions.

Appendix B-3

CLIMATE CHANGE MODELING DATA

This appendix accompanies Sections 3.4 and 4.4 of the Final Environmental Impact Statement (FEIS). It presents the results from the Model for Assessment of Greenhouse Gas-induced Climate Change (MAGICC) for the CAFE Alternatives for the Mid-1 and the Mid-2 Scenarios and compares the results to the Reference Case. The CAFE Alternatives use the A1B marker scenario from the Intergovernmental Panel on Climate Change (IPCC) as a reference case, equivalent to the A1B-AIM scenario in MAGICC. Tables B3-1 through B3-8 provide the results for the 2011-2015 CAFE Alternatives (Section 3.4 of the EIS) and Tables B3-9 through B3-16 provide the results for the MY 2011-2020 CAFE Alternatives (Section 4.4 of the EIS).

Mid 1 Scenario – 2011-2015

Table B3-1

Mid 1 Scenario Emissions and Emission Reductions (compared to the No Action Alternative) Due to the MY 2011-2015 CAFE Standard Alternatives from 2010-2100 (MMTCO2)

Alternative	Emissions	Emission Reductions Compared to No Action Alternative
No Action	195,501	0
25 Percent Below Optimized	182,893	12,608
Optimized	181,509	13,992
25 Percent Above Optimized	180,401	15,100
50 Percent Above Optimized	179,464	16,037
Total Costs Equal Total Benefits	177,743	17,759
Technology Exhaustion	170,829	24,672

APPENDIX D

Comments Received on Draft EIS

On June 26, 2008, the National Highway Traffic Safety Administration (NHTSA) issued a draft Environmental Impact Statement (DEIS) to analyze and disclose the potential environmental impacts of the proposed new Corporate Average Fuel Economy (CAFE) standards and reasonable alternative standards in the context of NHTSA's CAFE program pursuant to Council on Environmental Quality (CEQ) National Environmental Policy Act (NEPA) implementing regulations, U.S. Department of Transportation Order 5610.1C, and NHTSA regulations. On July 2, 2008, NHTSA published a *Federal Register* Notice of Availability, announcing that the DEIS was available. NHTSA's Notice of Availability also made public the date and location of a public hearing, and invited the public to participate at the hearing on August 4, 2008, in Washington, DC. On July 3, 2008, the U.S. Environmental Protection Agency issued its Notice of Availability of the DEIS, triggering the 45-day public comment period. In accordance with CEQ implementing regulations, the public was invited to submit written comments on the DEIS until August 18, 2008.

NHTSA received 66 comment letters and statements on the DEIS, and 44 people provided oral comments and statements at the public hearing. The transcript from the public hearing and written comments submitted to the agency are part of the administrative record and are available on the Federal Docket, which can be found at http://www.regulations.gov. To review these comments, enter the docket number "NHTSA-2008-0060" into the "Search Documents" field.

This appendix includes a copy of each comment document NHTSA received, including the public-hearing transcript. The transcript is presented first, followed by the comment letters submitted to the Federal Docket.

The Federal Docket assigned an identification number to each comment document. For this appendix, the document identification number is indicated in the upper right-hand corner of the first page of each comment document. The Center for Biological Diversity submitted its primary comment document (identification number 0570) with multiple attachments. The attachments (each of which was assigned a document identification number) were placed into the docket out of order. Because in this appendix we present the attachments in the order in which they were placed into the docket, regardless of the document identification number, the assigned numbers are not necessarily sequential.

C O N T E N T S

P R O C E E D I N G S

MR. KRATZKE: I'd like to welcome you to our public hearing on the draft environmental impact statement for our proposed corporate average fuel economy standards or CAFE rule for cars and light trucks for model years 2011 through 2015.

Before I start a brief overview of some ground rules, I'd like to ask you to please ensure that your cell phone is set to vibrate or silent. It can be distracting, especially if your ring tone is unique.

As you can see, we have nearly 60 people registered to present their thoughts and share their perspectives on this topic with us. So we'd like to get started right away. If you do the math of five minutes per speaker times 60, we have five hours worth of presentations.

Just so that it's clear to everyone, speakers will present in the order in which they registered with us. If you have not registered, we'd like to ask you to do so at the back of this room. We want to hear from everyone who has thoughts to share with us now.

If a speaker is not present for their scheduled time, they will be moved to the end of the list. They will be allowed to speak, but we are going to move ahead as quickly as we can to make sure we hear from everyone.

To begin, I'd like to introduce myself and the panel here to listen to your comments today. I am Steve Kratzke. I am the associate administrator for rulemaking for the National Highway Traffic Safety Administration. And my office is responsible for performing the environmental analysis for this rulemaking, and for doing the rulemaking on the corporate average fuel economy standards for those years.

On our panel today besides me we have four people who are much more aware than I am of our proposed rule and the draft environmental impact statement. And I'd like to introduce them.

On my right I have Julie Abraham, who is the director for our office of international policy, fuel economy, and consumer programs. Ms. Abraham led the effort to both put out our proposed standards for 2011 through 2015, and this environmental impact statement.

On my left I have Mr. Mike Savonis, who is the team leader for the CAFE rulemaking environmental impact statement team. Mr. Savonis is the one who has orchestrated and coordinated this large effort.

On the far right of the table is Ms. Carol Hammel Smith, who is a program analyst for NHTSA in our CAFE office. She specializes in environmental analysis. And on the far left we have Ms. Jessica Wilson who is an attorney in our chief counsel's office.

So we feel like we have the people here who really understand what we have put forward as our analysis, and we would like to hear the reactions of the interested public to that proposed analysis.

Our schedule for the day is going to begin with Ms. Abraham giving a brief overview of our environmental impact statement project. And then we are going to spend the rest of the day hearing from you.

We are going to have lunch from 12:30 to 1:30, and we will have breaks from time to time so that people don't have to run out and miss what's here.

Since we have a lot of people who would like to speak, I am going to call people up in groups of 12 to be seated near the podium. This will allow us to make a quicker transition when people are speaking.

We have a court reporter today here with us in front of the podium who is going to prepare a verbatim transcript of the testimony. The transcript will be available in our public docket.

We are going to videotape the proceedings as well, and so we ask for both of these sources so that when you begin to speak, please state your name and speak clearly for the record so that we can correctly identify you.

Due to the number of speakers, your comments are going to be limited to five minutes. We're going to notify you with a green card which will be held up in back when it is okay for you to start. And we will indicate to you when you have one minute remaining of your time by holding up a yellow card, and giving an audible remark of one minute.

When the five minutes are completed, we will hold up a red card and give an audible statement of time's up. At that point, we would appreciate it if you would wrap up your comments. We'd like to give everyone a chance to present today, so we're not going to be granting extensions of the five minutes of allotted time.

I would like to make clear that we're in the middle of a comment period. We want all of you to give us full comments where you can make sure that we have a record of what you believe needs to be conveyed. That is due in two weeks, on August 18th.

Today is for you to have five minutes to talk to the people who are going to prepare the environmental impact statement, and make sure that we understand your major points. We need to hold to that five minutes.

As this is our chance to hear from you, since you've already had the opportunity to read our hundreds of pages draft environmental impact statement, there aren't going to be questions and answers in this hearing. We want to hear from you.

We'd also like to thank you for your interest in this issue, and for taking the time out of your schedules to come to this hearing. We are really looking forward to hearing your perspectives, your suggestions, and your views of what are the most important things, good, bad, or just not covered in our draft environmental impact statement.

And with that, I would like Ms. Abraham now to give a brief overview of the draft environmental impact statement. I thank you.

MS. ABRAHAM: Thank you, Mr. Kratzke, and good morning everybody. I would like to begin by reviewing briefly the recent steps that brought us to this hearing.

In March and in April, NHTSA informed the public through notices in the Federal Register regarding our plans to prepare the draft environmental impact statement or for short, draft EIS.

First, on March 28th, we published a notice announcing our intent to prepare an EIS and requesting scoping comments. One month later we published a supplemental notice of public scoping.

The purpose of these notices was to request public views and comments on the scope of the agency's analysis, including the impacts and alternatives that the draft EIS should address, as well as to inform NHTSA of any available studies that would assist us in the impact analysis of global climate change and other issues.

On May 2nd we published our notice of proposed rulemaking, proposing fuel economy standards for model years 2011 through 2015 for both passenger cars and light trucks.

Under the proposal the average fuel economy for cars would begin at 31.2 miles per gallon for model year 2011, an increase to 35.7 miles per gallon for model year 2015; while the average fuel economy for light trucks would begin at 25 miles per gallon for model year 2011 and increase to 28.6 miles per gallon for model year 2015.

The agency also sought comment on a wide range of alternatives. On July 2nd we published a notice for this public hearing, and one day later, we published a notice announcing the availability of the draft EIS.

The draft EIS reflects our careful review and consideration of public comments that were provided, as well as the suggested studies. It compares the potential environmental impacts of the NHTSA's proposed standards and reasonable alternatives.

In developing its range of alternatives, NHTSA identified alternative stringencies that represent the full spectrum of potential environmental impacts. So for each of the alternatives, the draft EIS analyzes direct, indirect, and cumulative impacts, and analyzes impacts in proportion to their magnitude.

Based on climate models and other methods, the document analyzes the air pollutants, fuel savings, and greenhouse gas emissions for all alternatives. It also calculates the corresponding changes in sea level, precipitation, and temperature. In addition, it analyzes cumulative impacts on resources, ecosystems, human health, industries and settlements, among other things.

Following this public hearing, there will be an additional two week period as Mr. Kratzke indicated for interested parties to submit written comments on the draft EIS. I invite you to do so. This will ensure that we have the full benefits of your views and concerns.

The next steps will be our issuance of a final environmental impact statement, followed by a final rule for CAFE standards.

In conclusion, I and the rest of the panel look forward to hearing from you today. Thank you.

MR. KRATZKE: Thank you, Ms. Abraham. I would now like to call up the first 12 registered speakers and I would apologize in advance if I mispronounce your name. As someone named Kratzke, consonants are pretty tricky, so I will apologize.

The first 12 are, Julie Becker, Adam Lee, Dennis McGinn, David Westcott, Mark Cooper, Lena Pons, Eliza Berry, Ann Mesnikoff, Doug Molof, Matt Dernoga, Jazzlin Allen, and Sam Blodgett. So with that, I'd like to invite Ms. Becker to begin.

MS. BECKER: Good morning. My name is Julie Becker, and I am the vice president for environmental affairs at the Alliance of Automobile Manufacturers. The Alliance --

(Discussion off the record.)

MS. BECKER: My name is Julie Becker. I am the vice president for environmental affairs at the Alliance of Automobile Manufacturers.

The Alliance is a coalition of 10 car and light truck manufacturers, including the BMW Group, Chrysler LLC, Ford Motor Company, General Motors, Mazda, Mercedes Benz USA, Mitsubishi Motors, Porsche, Toyota and Volkswagon. We represent the largest group of companies directly impacted by NHTSA's CAFE rulemaking.

The Alliance shares with all Americans concerns about energy security and climate change. Last year Alliance members supported and they continue to support the Energy Independence and Security Act of 2007, a tough new national energy law that raises fuel economy to 35 miles per gallon by 2020, a 40 percent increase.

Higher mileage means low carbon, lower carbon dioxide emissions. Under the energy law, the United States auto industry will dramatically reduce CO_2 by 30 percent, which makes us the first industry to commit to such challenging CO_2 reductions.

The Alliance submitted in depth comments, and it's

tsh

a scoping plan for this draft EIS and will submit comments further on August 18th. Today, I would like to recap several key issues that we believe NHTSA needs to address before it completes its work on the EIS.

The first issue relates to NHTSA's inclusion of a no action alternative in its array of options. In our scoping comments, the Alliance noted that the 2007 energy bill does not allow for a no action option. Instead the energy bill sets a clear trajectory for increasing fuel economy standards for the span of a decade, and requires at least steady progress toward a 35 mile per gallon goal in model year 2020. We do not think it is appropriate for NHTSA to continue to rely on no action as its starting point.

The next issue relates to NHTSA's ability to defend it's position in ongoing or future litigation. Let me explain. NHTSA petitioned the Ninth Circuit to review En Banc the Center for Biological Diversity decision. One question before the En Banc panel would be whether the reviewing Courts lack the power to order the preparation of an EIS as opposed to ordering the agency to reconsider whether an EIS is appropriate.

The En Banc petition has not yet been acted upon. Since the position NHTSA took there was sanctions by the solicitor general. It would seem that NHTSA needs to reserve its right not to perform an EIS at all.

In order to preserve that right, NHTSA should also produce an environmental assessment, a finding of no significant impact for the current rulemaking. If NHTSA decides to proceed in any other manner, it risks wounding its own En Banc petition. So it is critical for NHTSA to take this approach.

In its comments, the Alliance noted that NHTSA already considers environmental impact and energy conservation when it sets CAFE standards. Therefore, CAFE rulemaking is the functional equivalent of performing an EIS.

Under the functional equivalence doctrine, an agency need not prepare an EIS if it has already undertaken the functional equivalent of an EIS as part of its rulemaking process. However, in its draft EIS for the CAFE rulemaking, NHTSA takes the position that it cannot rely on the functional equivalence doctrine.

In our view there is a solid argument for the functional equivalence doctrine here, and NHTSA should reconsider its position on this issue. At a minimum, NHTSA should assert the functional equivalence doctrine as an alternative basis that supports its final course of action.

I have three additional points to make before concluding. First, the draft EIS appears to be setting a significant precedent regarding analysis of the trans-boundary effects.

On page 1-11 of the draft EIS NHTSA argues it should analyze trans-boundary effects of the CAFE standards quoting a 1997 CEQ guidance document stating that agencies must analyze such effects underneath them. The statement seems directly at odds with judicial precedent and agency precedent, and we would like for NHTSA to reconsider this.

Second, the draft EIS incorrectly disregards the environmental impact of the fleet turnover effect, and this was explained in our scoping comments. The Alliance asks NHTSA to consider the fleet turnover effect, and the air quality impacts that will result from heightened CAFE standards.

Instead, NHTSA is treating this as an economic impact and an indirect one, which we don't think is appropriate.

Finally, I would note that our scoping, in our scoping comments, we asked NHTSA to consider how to construe the term ratably, a term that the Energy Dependence and Security Act of 2007 makes central. And so we would ask you to reconsider that issue as well.

Thank you for this opportunity to testify.

MR. KRATZKE: Thank you, Ms. Becker. Mr. Lee.

MR. LEE: Members of the committee --

(Discussion off the record.)

MR. LEE: Thank you. My name is Adam Lee. I am president of Lee Auto Malls, which is located throughout the State of Maine. I am a third generation car dealer. I have been in this business my whole life.

Our company was founded in 1936 by my grandfather, with a small Chrysler dealership. Today, we have 12 new and used car dealerships throughout the State. We are the number one seller of hybrid cars in the State of Maine. We are also the largest Dodge and Jeep dealer in the State.

Last year we sold approximately 7,000 new and used cars. I am not an economist, nor am I a scientist. I don't know how to build a car, or run an automobile plant. I've never even changed the oil in my car. However, for most of my life I have been selling new and used cars and trucks. I still talk to customers every single day.

I came to Washington today because when I listen to the news I sometimes feel like I must be the only person in the car industry actually talking to real customers. Here is what I hear every single day.

How long is the wait for a Prius. Do you have any Honda Fits in stock? Why doesn't Chrysler offer a car that gets better than 30 miles per gallon? Or the other types of calls I get, what's my Tundra worth? Can I get rid of my Suburban?

The answer to these questions are simple. The wait for a Prius is six months. I have no Fits or Yaris. Your

Suburban is not worth enough for you to be able to trade out of it, because generally you owe more than it's worth.

Consumers want to buy vehicles that get more than 30 miles per gallon. And I'm not just talking hybrids. Car dealers have people waiting for good old fashioned small cars that get good fuel economy. They've been demanding them for years with very few choices, and almost no choices from Detroit.

This is not a new situation, but with gas at $4 per gallon, the demand is overwhelming and the lack of choices is dramatic.

Our big Chrysler dealership in Portland, Maine, has about half as many sales people as we had around a year ago. We have fewer people working in the office, fewer people working in our service department. They are no longer employed because we don't have the cars to sell that people want to buy.

This means fewer sales people frequenting the corner store, the dry cleaners, the hardware store. It's bad for the economy. General Motors just announced a loss of $15.5 billion. That's for the quarter. Ford just announced an $8.7 billion loss. Standard & Poor's just lowered to (indiscernible) the three's credit rating to junk status, and even Toyota who can do no wrong is shutting down its truck plant in Texas for three months. What they are doing is not working.

So how did we get here? In 1975 Congress mandated our first fuel economy standards. Unfortunately, in the last 20 years, these standards have not changed a bit. NHTSA could and should have done more. I believe our lack of progress is largely a regulatory failure.

Anyone who watches the auto industry knows that the manufacturers have never done anything in the name of safety or the environment unless they are forced to, whether it's seat belts, air bags, catalytic converters, Detroit has always insisted that they could not pay for them, until it becomes mandated, at which point you would think they invented the word unleaded gas.

NHTSA plays a real role in determining what our fuel economy will be. You analyze the impact of CAFE on Detroit. And I think that your assumptions are based on incorrect data. Gas costs $4 a gallon, not $2. The new technologies are coming down in price. Consumers have changed their habits and their view of the future.

Now is the time for NHTSA to act. Don't drag your feet. Don't look to Detroit for answers. Look to the American consumers. They are demanding change. They've cleaned our shelves of small cars, and they are desperate to trade in their gas guzzlers.

I've been selling Prius' since they came out seven years ago, and since that time every Toyota dealer I know has been selling them for list price and making a very nice profit. Demand is so strong, people have stopped negotiating. This is a car dealer's dream, a car people want so badly they don't negotiate.

It's frustrating to have a car sell this well and not have enough of them. I can't blame Toyota for having a hit, however, I can blame Detroit for not having one. If you want to know how bad it really is, read Automotive News. This is an editorial from two weeks ago.

It's distressing that some auto makers are back in Washington whining about meeting new fuel economy standards at a time when their customers are demanding vehicles that exceed the regulatory mandates. These cars that Detroit bet their future on and mine are not selling.

For over 70 years my family has been selling American made cars. I am a third generation running this family business. My 11 year old son thinks he will do what his father, grandfather, and great grandfather did to earn a living, sell American cars. Will there be anyone left still making cars in Detroit? We need your help. Thank you.

MR. KRATZKE: Thank you, Mr. Lee. Mr. Dennis McGinn.

MR. McGINN: Good morning. I'm retired Admiral Dennis McGinn. Mr. Kratzke, members of the panel, thank you for the opportunity to share my views which are based on over 35 years of service to the nation in the United States Navy, and more recently as a senior executive with extensive experience with the Science, Technology of Energy, Transportation and the Environment.

The EPCA requires the Secretary of Transportation to establish average fuel economy standards and when setting "maximum feasible" fuel economy standards, the secretary is required to, "consider technological feasibility, economic practicability, the effect of motor vehicle standards of the government on fuel economy, and the need of the United States to conserve energy."

Today I'd like to focus on that last requirement, and specifically on the multiple national security costs of our present level of oil dependency. In the interest of time, and in consideration of the many witnesses schedule to appear before you, I will give you my bottom line up front.

Our continued dependency on oil constitutes a clear and present danger to our national security, economically, militarily, and diplomatically. These dangers involve real, quantifiable costs, and these costs do not appear to be adequately included in your assumptions for the proposed fuel economy rule.

As a result, your draft environmental impact statement is at best incomplete, and more importantly, fundamentally flawed by its reliance on outdated data and unsupported assumptions about the real costs of this nation's ever growing consumption of oil. Erroneous assumptions based on old data inevitably leads to fundamentally flawed conclusions.

Ignoring these costs is just not a mistake. It is a threat to our national security because it precludes fuel savings our citizens and nation critically need at this moment in our history.

Our burgeoning demand for oil weakens U.S. diplomatic leverage around the globe, burdens our armed forces, and leaves the United States' economy vulnerable to unpredictable price spikes and an ever growing trade imbalance.

Taken together, these dynamics create a daunting national security challenge that must be met immediately. With oil at over $130 a barrel, over a million dollars each minute is draining out of our economy, increasing our trade deficit, creating huge opportunity costs, and most significantly, putting money in the hands of regimes that are hostile to our interests.

OPEC recently warned that prices, oil prices would experience an unlimited increase in the event of a military conflict involving Iran over its nuclear program. A very real consequence of such confrontation is that Iran, in a bid to preempt or respond to U.S. military action would close the Straight of Hamus through which 20 percent of the world's oil supply passes. The impact would be swift and sure. Unprecedented spikes in oil costs, and a deep and lasting effect on the U.S. and world economy.

The ongoing impact of our oil dependency already threatens our national security economically. We lose over $35 billion from our economy every month, and oil imports now account for over half of our annual trade deficit. We are exposed on a daily basis to oil price shocks and supply disruptions.

Regardless of how they are caused, by global market dynamics, natural disasters, terrorist attacks, or politically motivated oil embargos, the trends of our growing oil demand in a business as usual mode will make those price shocks much more frequent, deeply felt, and longer lasting.

In addition, there are national security costs and risks involved in addressing climate change. Last year top retired three and four star military leaders in a report from the Center on Naval Analysis, global warming poses a "serious threat to America's national security, acting as a threat multiplier for instability in some of the world's most volatile regions, adding tension to stable regions, worsening terrorism, and likely dragging the U.S. into fights over water and other resource shortages.

Congress set a floor and not a ceiling on CAFE standards. Your rulemaking is intended to take a host of factors into account to set the right level. Throughout our history Americans have successfully met critical challenges in both war and peace. Building on a new, clean energy economy has become one of the greatest challenges and opportunities of our time.

The key questions for all of you and your colleagues in making this rule as you go forward are, how will the actions on CAFE by this agency and this administration be viewed in 10 or 20 years? Will we be able to look back and say that a bold, comprehensive, and enlightened mandate produced substantial oil savings, increased our national security, and helped our economy and significantly reduced carbon emissions.

We have less than 10 years to change our oil dependency course in significant ways. Our nation's security depends on the swift, serious, and thoughtful response to these challenges, and by the significant impact your deliberations rulemaking will have on carrying out the intent of Congress and to the benefit of the American people. Thank you, Mr. Kratzke, and members of the panel.

MR. KRATZKE: Thank you, Admiral McGinn. Mr. David Westcott.

MR. WESTCOTT: Good morning. My name is David

Westcott. I'm chairman of the NADA regulatory affairs committee, and a Buick, Pontiac, GMC, Isuzu, Suzuki dealer in Burlington, North Carolina.

NADA represents 19,000 franchise automobile and truck dealers who sell new and used vehicles in this country. While together we employee in excess of 1,100,000 people nationwide, a significant number are small businesses as defined by the SBA.

Before I get specific in my comments on the draft environmental impact statement, permit me to give you a feel for what is going on in the new vehicles sales marketplace. July was one of the worst months in the history in the last two decade in new vehicle sales.

This was due to a number of factors, including the sub-prime lending crisis that has now hit our industry. Consumers have less cash. Consumer debt is up. Financial institutions are much tighter on credit. Negative equity for consumers wanting to trade is at an all time high, often as much as $15,000 per vehicle. There are very few trade-ins on new vehicles. And used vehicle sales are far outnumbering new vehicle sales.

I urge you to keep these market realities in mind as you proceed with considering the testimony of everyone today and the issues you have to decide.

In the past, NHTSA has consistently and adequately

tsh

assessed and accounted for the potential environmental impacts of its proposed CAFE standards. NADA therefore disagrees with the 2007 Ninth Circuit Court of Appeals decision in Center for Biological Diversity v. NHTSA, which reviewed NHTSA's '06 reform light truck standards, and suggests that it is incumbent upon NHTSA to conduct a formal EIS in conjunction with its model year 2011-2015 proposal, CAFE proposal.

I understand that NHTSA has petitioned the Ninth Circuit for rehearing, and the EIS issue is awaiting a response.

Importantly, CAFE standards equate the greenhouse gas emissions in that CAFE compliance is measured by capturing greenhouse gases emitted by regulated motor vehicles. Thus the draft EIS appropriately suggests that model year 2011 through '15 [sic] proposal likely will result in the overall motor vehicle greenhouse gas emission reduction below what will occur without standards.

Of course, this conclusion assumes that purchasers will buy new vehicles covered by CAFE proposal, and hereby bring them into the fleet at the rate assumed by NHTSA and that once introduced into the fleet, they will be driven to the same degree that NHTSA has assumed.

To that extent, purchasers do not buy -- to the extent that purchasers do not buy vehicles regulated by the

tsh

CAFE proposal and bring them into the fleet as predicted, whether due to their higher cost or lack of desirability, the CAFE proposal will necessarily fail to achieve this hoped for level of environmental performance.

This jalopy affect phenomenon recently was demonstrated by the failed introduction of the '07 model year medium and heavy-duty truck rules governed by the new EPA emissions mandates that increase their costs and arguably compromise their fuel economy and reliability.

Similarly, to the extent vehicles regulated by the CAFE proposal are used by NHTSA predicts after introduction into the fleet, the proposal will necessarily fail to achieve its expected level of environmental benefit. Due to the rebound effect, vehicles with lower operating costs predictably will be used more than the vehicles they replace.

Environmental impacts that correlate with miles driven, traveled, such as those associated with greenhouse gases will be impacted to the degree of any such rebound effect, reducing any delay or forecast in environmental performance benefits.

In addition to recognizing the critical role of fleet turnover in vehicle miles traveled, play with respect to environmental performance, the final EIS should consider only those measured, real and measurable environmental impacts. Thank you very much for commenting time.

MR. KRATZKE: Thank you, Mr. Westcott. Mark Cooper, please.

MR. COOPER: Good morning. I am Dr. Mark Cooper, director of research at the Consumer Federation of America. We appreciate the opportunity to appear today and commend the National Highway Traffic Safety Administration for holding this hearing. My comments are sponsored by CFA and over two dozen of its member groups.

We urge the administration to hold hearings all across the country, not just here in Washington in the dead of August, so the public can weigh in on the issue of fuel economy, which is vital not only to consumer pocketbooks, but also to national security and the environment.

Consumer attitudes and behavior toward fuel economy play a vital role in NHTSA's market model and analysis, and as we show in our comments, NHTSA has completely misjudged the consumer. There would be no better way for NHTSA to correct this flaw than to hear directly, in person, from the people who it has failed to comprehend in its analysis.

There are two problems in the draft environmental impact statement that render it woefully inadequate to address the public policy of the act. First, the underlying analysis is so fundamentally flawed that the agency has not considered an appropriate range of policy options for which the environmental impact should be evaluated.

Erroneous assumptions about market fundamentals, about consumer behavior and attitudes towards fuel economy, auto making capabilities to incorporate fuel savings technologies, and the price and value of energy have led NHTSA to center its analysis on a level of fuel economy that is so low that it sheds little light on what the environmental impact of a reasonable fuel economy standard would be.

Consumers are looking for higher mileage in new vehicles today than NHTSA has mandated for seven years from now. The product plans on which NHTSA based its rule seven years in the future have already been torn up by the automakers, but belatedly recognize the shift in consumer behavior.

The mix of cars and trucks that NHTSA projects, there's no relationship to the vehicles that consumers are buying. Rules that are not connected to reality violate the act and the administrative procedures act.

If you don't think that people will buy and drive more fuel efficient vehicles, you must be living under a rock.

The crucial rule of higher fuel economy standards is to push the automakers to deliver vehicles that consumers want, and to push the auto industry to the maximum technologically feasible and economically practicable level.

NHTSA has failed to do so.

The second problem in the draft environmental impact statement stems from the fact that NHTSA takes a fundamentally flawed approach to its externality analysis. This was evident in the analysis of the military and strategic externalities in the proposed rule. There NHTSA engaged in reasoning that can at best be described as blind incrementalism.

Rather than see improvements in fuel economy as part of a broader solution to the national oil addiction, NHTSA argues that the cost to rule alone cannot solve the problem, it does not deserve to be counted as making a contribution to the solution.

Implementing a law entitled the Energy Independence and Security Act NHTSA arrived at the outrageous conclusions that oil consumption has no military or strategic value whatsoever.

The analysis of environmental impact suffers from the same affliction, because improvements in fuel economy alone do not solve the climate change problem. They are shown to have zero effect on the damage that global warming will do. Yet every reasonable analysis of the big picture and the global impact of greenhouse gas emissions recognizes that the reduction of emissions in the transportation sector must play a large role in the overall solution. Indeed, because of the nature of the sector, it is vital to get the maximum contribution from transportation sources.

NHTSA's approach embodies a myopic bias against action. Because no individual policy can solve the problem, this approach will reject every policy measure individually, even though taken together they can actually do the job. In NHTSA's view the whole is not even equal to the sum of the parts.

The challenge of national security and environmental impact that emanates from NHTSA's addiction, the nation's addiction to oil, are global and multifaceted. The analytic framer must recognize that fuel economy standards are an important part of the broader issue.

Our recommendation that you increase the level of the standards for 2011 and 2012, and that you withdraw the 2013 through 2015 proposals so that you can fix the fundamentally analytic flaws in the analytic framework and the erroneous economic assumptions is all the more compelling in light of the mounting evidence that the rule NHTSA has proposed fails to be a reasonable standard that comports with the act. Thank you.

MR. KRATZKE: Thank you, Dr. Cooper. Lena Pons, please.

MS. PONS: I'm Lena Pons, policy analyst at Public Citizen. We have a number, we appreciate the opportunity to testify, and we have a number of concerns about the draft environmental impact statement which will fall into three categories.

The first is the range of alternatives does not constitute the range of alternatives envisioned under the National Environmental Policy Act, and does not meet the requirements under the regulation.

Under the regulation set forth under the National Environmental Policy Act, agencies are required to consider a range of alternatives that include all reasonable regulatory alternatives. The regulatory alternatives that are considered in this proposal effectively are a confidence bound around the optimized scenario proposed in the regulation.

Additionally, under the regulations, agencies may consider regulatory alternatives that are not in the jurisdiction of the lead agency, which would include more protective types of regulations such as greenhouse gas regulations for motor vehicles, such as those envisioned by the State of California and other states, and also part of the EPA's proposed greenhouse case, economy wide greenhouse gas regulations.

Additionally, the no action alternative should not be considered to be an extension of the situation as it stands, but should be a reflection of what would happen were there no regulatory intervention.

Other reasonable alternatives would include a situation wherein there was additional increases in fuel economy standards beyond the period of the Energy Independence and Security Act, which would require only that vehicles reach a standard of 35 miles per gallon for the combined fleet, cars and light trucks by 2020.

However, given the fact that there are significant market incentive and also environmental incentive to extend the standards beyond that level, then there is a likely, there's likely a reasonable alternative to consider what would happen if you had standards that extended beyond that level.

Considering that this is a new type of environmental impact statement, because it considers global impacts, it's very important that the agency put the impacts in a proper context. The agency has not put the environmental impacts into a proper context, considering the issues of global warming.

Regardless of the target, NHTSA needs to provide some means of comparing the various alternatives. The way the draft environmental impact statement is currently contextualized, NHTSA states that fuel economy standards alone cannot stop global warming. But the issue is not whether fuel economy standards alone can stop global warming.

The issue is to evaluate various environmental impacts of the various regulatory alternatives.

NHTSA has not presented a regulatory alternative that would result in actually reducing greenhouse gas emissions from motor vehicles. This is unacceptable. NHTSA has the responsibility to use its expertise to pose a theory wherein there is a regulatory alternative that could result in producing impacts that actually reduce greenhouse gas emissions from the motor vehicle sector.

And considering again that there is leeway for the agency to consider impacts that are the result of regulations that are outside of the agency, lead agency's jurisdiction, then it could look at things that would address vehicle miles traveled reductions, or other types of policies that might, as a whole, result in reductions that will result in improving the situation in terms of global warming, which again goes to the issue of context.

It is very important that this environmental impact statement reflect the situation that we are currently in.

With my final minute I would like to make some statements about the Volpe model. All of the regulatory alternatives that are considered in the draft environmental impact statement are the result of modeling using the Volpe model. This is problematic because the Volpe model does not completely look at all of the available technologies. It does not look at, and it applies various optimization factors which do not reflect what the most aggressive possible control regulations would be.

Additionally, the Volpe model bars certain types of techniques, such as down weighting and performance reduction, which may seem like strange things to do, because we've traditionally considered them to be problematic. However, given the significant dangers to the environment as a result of global warming, it's important to consider these things as well. Thank you very much.

MR. KRATZKE: Thank you, Ms. Pons. Ms. Eliza Berry.

MS. BERRY: Good morning. My name is Eliza Berry. I grew up in New York and I'm currently a college student in Minnesota. I'm here today because like many of my peers I'm incredibly concerned about global warming.

The Intergovernment Panel on Climate Change reported in the 2007 fourth assessment report that the best action plan for avoiding the most severe impacts of global warming, such as widespread species lost and global declining food production requires reducing global greenhouse gas emissions by 80 percent by the year 2050.

The report states that to get on track towards achieving this goal, global greenhouse gas emissions must peak in no more than 10 years. As a 21 year old, I am fully aware that this 2050 deadline for cutting the majority of greenhouse gas emissions will occur during my lifetime.

With its draft environmental impact statement, NHTSA has unfortunately sent the message that global warming is such a massive problem that the agency can do little about it. The report says that despite the fact that the transportation sector is responsible for 20 percent of U.S. greenhouse gas emissions, the statement concludes that we should not increase fuel economy standards from 31.6 miles per gallon to 35 miles per gallon in 2015, because doing so will not reduce global ocean temperature in the year 2100.

I am here today because young people like me do not care to live a world where devastating global warming impacts are considered to be simply inevitable.

The draft environmental impact statement does not use the appropriate scale with which to measure the benefits of an increase in fuel economy standards. This scale has only allowed NHTSA to prove that a 3.4 mile per gallon increase in vehicle efficiency in the U.S. is not going to be the one thing to save the entire planet from global warming. I don't think that very many people would be surprised by this conclusion.

By measuring the importance of a shift in fuel economy standards like this, NHTSA has fundamentally missed something. Few people would claim that there is one silver bullet to solving global warming. Rather, we need to do everything in our power to cut greenhouse gas emissions in all sectors, the transportation sector included.

Together these seemingly small changes will make a major difference. And if the U.S. leads the way in cutting emissions, other countries will follow, thus making an even greater difference on a global scale.

I would like to ask NHTSA to acknowledge the power of collective action and take responsibility for greenhouse gas emissions from the transportation sector. As I have explained, the intergovernmental panel on climate change has emphasize the importance of requiring that greenhouse gas emissions reach their peak in no more than 10 years.

NHTSA is currently making a decision that will profoundly influence our emissions during the next 10 years and beyond. NHTSA should therefore contribute to the effort to peak emissions sooner rather than later. This means adopting the highest fuel economic standards economically and technologically possible.

In summary, I would like to ask NHTSA to reevaluate the conclusions drawn from their draft environmental impact statement, and encourage NHTSA to require a 35 mile per gallon fuel economy standard by 2015. Thank you for your time.

MR. KRATZKE: Thank you, Ms. Berry. Ann Mesnikoff, please.

MS. MESNIKOFF: Good morning. My name is Ann Mesnikoff. I'm a senior Washington representative with Sierra Club's global warming and energy program, and I am testifying today on behalf of Sierra Club.

If there ever was a need of the nation to conserve oil it is now. The headlines daily remind us of the consequences of oil dependence. Americans send nearly $2 billion dollars a day overseas for oil. Many can no longer afford to fuel the gas guzzlers they purchased, nor can they sell them as consumers flock to smaller cars.

Food prices are rising. Dollars are being drained from our economy, and are not being spent in our local businesses or in our communities, wrecking economic havoc. It took decades for Congress to finally pass the first mandated increase in fuel economy since the original CAFE law was passed. After writing standards language, NHTSA is finally ramping up mileage standards.

In the meantime, the industry has become addicted to selling SUV's and we have become addicted to oil. The biggest single step we can take to curbing global warming, saving oil, and helping consumers at the pump is to make new vehicles go farther on a gallon of gas.

But we see in the NOPR and the DEIS that fuel economy is only the biggest single step if the right standards are set and evaluated in the right context. Raising fuel economy standards to at least 35 miles per gallon in 2015 is a key step to curing our oil addiction and reducing global warming pollution.

I will make three points today and submit written comments for the record. First, Sierra Club's written comments and the proposed rule address the flawed process for arriving at the 31.6 mile per gallon proposed standard. The proposed rule and the PRIA both show that the gas prices are major forces in setting fuel economy. NHTSA short changes America by using gas price assumptions that are far too low, a price for carbon that is randomly selected, and artificially constraining technologies.

NHTSA must set the right optimized standard and then recalibrate the other bounds. The 35 mpg target in 2020 is a floor not a ceiling. The law directs that the standards be what is maximumly feasible. How can the public have confidence in NHTSA, that NHTSA is setting the right standards when some of the key inputs in its analysis are flawed.

Second, can the public have confidence in the range of options considered in the DEIS. NHTSA strictly adheres to a 35 by 2020 standard. At several points NHTSA recognizes the two critical words which proceed 35 in the 2007 energy bill, the words "at least."

In other places NHTSA says the standards must be set to 35 by 2020. NHTSA notes that the 2016 to 2020 standards are foreseeable in the draft environmental impact statement, but the law provides them for the maximum feasible thereafter. Increases beyond 2020 are foreseeable, perhaps just as foreseeable as the VMT increases NHTSA presumes through 2100.

NHTSA should first use more accurate values for gasoline prices and other inputs to justify a 35 in 2015 standard, and increases beyond that with greater hybrid penetration, accelerated introduction of plug-in electric hybrid vehicles, and other technologies.

The DEIS is premised upon a flawed proposed standard and the scenarios that must be addressed should be fixed before a final standard is issued and a final EIS is issued.

The third point I would like to raise concerns -- are concerns [sic] about the draft environmental impact statement and whether it meets the primary function to inform the public that the agency has indeed considered environmental concerns in its decision making process.

In this case the agency does not give a fair or reasonable evaluation of the environmental impacts of the proposed standards, nor does NHTSA provide a context that reasonably informs the public.

The draft environmental impact statement takes the real differences between the options considered and runs them out so far to 2100 that they cannot meaningfully be differentiated or evaluated. Faster fuel economy increases will help the U.S. cut the 20 percent of CO_2 emissions that come from vehicles.

The difference between 35 in 2015 and 35 in 2020 is real. It is worth noting that the draft environmental impact statement reveals that this one policy could affect climate in 2100. The problem with NHTSA's analysis is that if we hit 700 parts per million plus, referenced in the DEIS, we have not averted dangerous climate change.

There is no requirement that NHTSA run its analysis through 2100. NHTSA notes that it's Volpe model estimates emissions reductions through 2060. The agency provides as a simplifying assumption, annual emission reductions from 2061 to 2100 were held constant. NHTSA should assess how the correct scenarios will impact emissions from cars and trucks in a time frame that is meaningful to the public, and within the context of science, not simplifying assumptions.

Fuel economy is only one policy in the tool bag. It will diminish the 20 percent of CO2 that comes from cars and trucks, but we must achieve an 80 percent reduction below 2000 levels by 2050 if we are to avert dangerous climate change.

For too long, the industry has fought higher fuel economy standards and successfully constrained NHTSA and Congress. The purpose of fuel economy law has been undermined for too long, and NHTSA must not perpetuate this by setting tomorrow's standards using yesterday's gas prices.

Before NHTSA finalizes its standards and the EIS, it must ensure that it's meeting the intent of the CAFE law and of NEPA. We must end our addiction to oil. Raising fuel economy standards to at least 35 in 2015 will speed up oil savings, speed up CO_2 reductions.

Finally, NHTSA must evaluate the environmental impacts of these standards in science-based context that informs the public. Thank you for this opportunity.

MR. KRATZKE: Thank you, Ms. Mesnikoff. Mr. Doug Molof.

MR. MOLOF: Good morning. My name is Doug Molof. I'm here as a concerned young citizen that has seen people in my home state of Texas struggle over the past several months to fill up their cars with gasoline.

In Texas there is no real public transportation alternative. The state is large and people are regularly forced to travel long distances on a regular basis.

NHTSA must act now to address the devastating environmental and economic impacts of America's growing oil dependence and rising gas prices by setting fuel economy standards at the maximum feasible level.

The agency's current proposal relies on unrealistic gas price assumptions which result in insufficient fuel economy levels. The agency's proposal assumes future gasoline prices to be only $2.25 per gallon in 2016, when American future gasoline prices -- when American consumers are already paying prices nearly twice as much today. In fact, since NHTSA first released its draft CAFE rulemaking, the price of gasoline has jumped by over a dollar.

NHTSA's own analysis shows that between 2011 and 2015 significantly higher standards are technologically feasible and economically practical when higher gas prices are used. NHTSA's final rule should be, at a minimum, consistent with the analysis provided in the preliminary impact analysis that accompanied the notice of proposed rulemaking.

NHTSA's use of the low cost energy estimates is arbitrary and violates the agency's statutory charter to impose mandatory maximum feasible fuel economy standards based upon a review of economic and technological feasibility.

The high gas price scenario yields cost effective and technologically feasible standards that will help meet the nation's need to conserve energy, and will help lower gas prices for the average American consumer. NHTSA should ensure that final standards are set using this value at a minimum.

NHTSA's draft EIS fails to analyze, also, the benefits of greenhouse gas emissions reductions through various fuel economy standards in the proper context. Not surprisingly, when NHTSA tries to determine the difference in global ocean temperature rise in 2100, resulting from a 31.6 mile per gallon standard in 2015, versus a 35 mile per gallon standard in 2015, statistically there is no difference.

But emissions from the transportation sector in the United States account for roughly 20 percent of our country's greenhouse gas pollution. And as any projection, decreases in greenhouse gas emissions arising from increased fuel economy standards can never be greater than this. [Sic]. These reductions should be considered as a proportion of the 20 percent, not as a proportion of the entire planet's combined carbon admissions.

This can simply overwhelm any measurable progress. Success and progress should be measured by how close these fuel economy improvements get us to reducing the transportation sector's carbon emissions by 80 percent in 2050.

To do otherwise fails to realistically evaluate vehicle emission reductions as a key part of the overarching strategy to curb global climate change.

The debate is over on climate change. The scientists and the American public agree and have reached the same conclusion. It's happening now. We are already feeling the vast effects and we must act immediately to stave off the worst effects. Thank you so much for the opportunity to testify.

MR. KRATZKE: Thank you, Mr. Molof. Matt Dernoga, please.

MR. DERNOGA: Hi. My name is Matt Dernoga. And I wanted to first thank the National Highway Traffic Safety Administration for holding this hearing, and allowing me to give my input on the critical decision of what our CAFE standards should be set to the upcoming decade and beyond.

It's difficult to know where to begin because I find all this very perplexing. I find it perplexing that NHTSA would aspire to only a mere 35 miles per gallon by 2020, the bare minimum of what is required by the Energy Independence and Security Act.

I am confused that American auto makers would fight raising fuel economy standards, given the dire fiscal situation they find themselves in, as a direct result of their stubbornness.

I don't understand why the implications CAFE standards have on climate change do not appropriately reflect NHTSA's decision-making. [Sic].

Finally, I am baffled that our new CAFE standards are based on the presumption that the cost of a gallon of gas will be only $2.25 by 2016. I wonder if we are living on the same planet.

I'm going to hazard a guess that there have been hearings like this in the past, that years ago when the NHTSA was considering raising fuel economy standards they decided against it based on the presumption that gas would be cheap through the opening decade of the 21st century. NHTSA chose to assume the best, and failed to prepare America for the reality that awaited it.

As a result, we have become more dependent on oil than ever before, exporting hundreds of billions of dollars overseas each year with some of it going to hostile countries. Our economy is sputtering since everything costs more as a result of high fuel prices.

Businesses are having trouble staying afloat. Truckers can no longer make a living. All of the companies are posting billions of dollars in losses while cutting jobs, and food prices have risen because of shipping and production costs.

Americans find themselves barely able to hold their heads above the tide. The NHTSA is determined to respond to their mess by pushing their heads below that tide and holding them there. The notion of $2.25 a gallon gas by 2016 is laughable. It's a joke I could tell in a comedy club. There's no way that anyone in this room actually thinks that this will be the price. I'd be willing to bet anyone any amount that the price will be higher. Would anyone here take that bet?

NHTSA has already gambling, though. They're gambling with the future of our country. Planning our CAFE standards around the assumption of $2.25 a gallon of gas isn't a game. It's dangerous. You're playing a Russian roulette with the American economy. You're holding a loaded gun to its head and pulling the trigger with the hope that it fires a blank.

If you haven't noticed, our economy, our infrastructure, our lives and yes our cars are designed on the premise of cheap gas. That has to change or we will face hardship many times greater than what we are facing now.

I know that we can meet higher CAFE standards than 31.6 miles per gallon by 2015. I know this not only because of NHTSA's own analysis, but because I know the strength, determination, and good will of the American people. It's unnatural for us to aspire to meet only the bare minimum of what is required. That is not the American way. We do not reach for the ceiling. We reach for the stars.

The NHTSA needs to weigh the risk of being wrong by doing too little versus the reward of doing too much. It also needs to examine its conscience and factor in the implications of climate change appropriately in its decision making.

But undertaking those two simple tasks, I have faith that we can do something about CAFE that we have never done before, the right thing. Now or never is a false choice. If you love this country and if you love your children, the time is now. Thank you.

MR. KRATZKE: Thank you, Mr. Dernoga. Jazzlin Allen.

MS. ALLEN: Good morning. My name is Jazzlin Allen and I am a U.S. (indiscernible) intern and a resident of western New York, whose savings is being bled out by major oil companies and their outrageous gas prices.

This summer and over the past few years I have experienced how high fuel costs and the lack of more fuel efficient vehicles have affected the financial health of my state and this country. Even the ability for these people to feed their families has been affected.

More personally, gas prices have had an affect on my family. As a recent college graduate, I worked an entry level position and juggled the bills on my own. I have often had to choose between eating lunch and filling my gas tank just to get back to work for the next week. Without access to the funds to afford a more fuel efficient vehicle, mainly because no one wanted to give me a fair price on my SUV, and my only support system being my single working class mother, I was forced to continue to invest in the most lucrative rip off scheme in the world, big oil companies.

Where is the return on my investment? Where is the concern for the financial security of hard working Americans? Why isn't there a stricter system of check and balances?

Fuel prices are even adding to this nation's health crises, with common foods like milk, eggs, and vegetables being at record high prices, my family cannot afford many of these healthy everyday items. I mean, these billion dollar oil companies are snatching the food off American tables and out of our mouths.

The next time you visit New York City, make sure you close your eyes as the wind blows. The air is thick, polluted, and unpleasant to inhale. The affects of smog are incredible. As a person with asthma, I can no longer consistently frequent the city because the air is so dense, dirty and disgusting.

I am no scientist, and I am not able to scientifically analyze just how much global warming has affected the State of New York, but I know that I can feel the effects because I am living with them. I can feel them when I breathe the air, and I am often stuck in the car because of the congested and somewhat unreliable public transportation system.

As many other people have came [sic] and testified before you, the debate over climate change has ended, and we are feeling its effects on our communities today. It is more important now than ever to curb our greenhouse gas emissions and do our part to mitigate the affects of global climate change.

NHTSA's current proposed standards for cars and light trucks put us on a path to increasing fuel economy to only the bare minimum, 35 miles per gallon by 2020, required by the Energy and Security Act of 2007. NHTSA fails to take full advantage of available fuel saving technologies, and must reconsider the proposed standards and use its statutory authority to meet the urgent need of the United States to reduce carbon emissions, conserve oil, and meet the growing demand of American consumers for vehicles that go farther on a gallon of gas.

I'm pleading to you on behalf of American families and our economy to reconsider your EIS report. Thank you for your time.

MR. KRATZKE: Thank you, Ms. Allen. Mr. Sam Blodgett.

MR. BLODGETT: Good morning. My name is Sam Blodgett, and I am testifying today as a public citizen of the United States of America.

I have come here to voice my concerns with the National Highway Traffic Safety Administration's recent draft environmental impact statement or fuel economy standards, or CAFE.

I strongly believe that NHTSA must raise CAFE standards to 35 miles per gallon by the year 2015. Failure to do so would be a failure of the [sic] American people who are in desperate need of relief from rising gas prices.

I am a California native, born and raised. Although my parents divorced when I was just three years old, I grew up with parents who both had a real presence in my life. Soon after their divorce, my mother and I moved to a new city, roughly 180 miles from my father.

Despite the distance, my parents took turns driving seven hour round trips to ensure that I could grow up with both my mother and my father. And while I thank God they got divorced when they did, and you would feel the same if you knew them, I am forever indebted to my parents for sacrificing their time, energy, and money to keep my family together. I could not have come as far as I have without them.

So, why share this story with you? Gas prices, gas prices, gas prices. $1.50 gas, while not cheap, enabled my parents to make that 360 mile journey without burning a whole in their wallets. That same journey, given current gas prices and CAFE standards, would be inconceivable now.

My mother, who worked one-third time [sic] to raise me, could never have afforded that drive with $4.50 gas. Current gas prices would have forced my parents to choose between bare necessities and their child. American families should never have to make that choice.

Economists agree $2, even $3 gas price days are over. Your environmental impact statement must reflect this new reality. In your draft EIS you analyze two price projections for the cost of gasoline; one that predicts $2.25 [sic] gas prices by 2015, and another that predicts $3.14 [sic] gas prices by 2015.

In your EIS you chose to use the lower price estimation. Given current gas prices, this was an obvious misstep. It is only prudent to use the higher cost estimation. Even it undervalues gas by almost a dollar.

According to your analysis, if gasoline is $3.14 by 2015 then higher fuel economy standards are both technologically feasible and economically practicable. If true, then it is nonsensical to continue as planned.

You must raise CAFE standards to 35 miles per gallon by 2015. Doing so would save Americans more than 76 billion gallons of gas over five years, according to your own analysis. As an American, that's the first bit of good news I've heard in a while.

And a quick reminder, failure to utilize the higher cost projection violates NHTSA's statutory charter to impose mandatory feasible fuel economy standards based on economic and technological feasability.

But here's the bottom line. Assuming $2.25 gas in 2015 is insulting to the American people. Americans are craving gas price solutions. NHTSA has the power right now to relieve some of our pain at the pump. Passing up this opportunity would be shameful.

The National Highway Traffic Safety Administration is part of the federal government that was created by our founding fathers to serve Americans. By failing to raise efficiency standards, NHTSA is failing we the people. So do what's good for America. Raise CAFE standards to 35 miles per gallon by 2015 or as my mother would say, let's get this show on the road. Thank you.

MR. KRATZKE: Thank you, Mr. Blodgett. And thank you to the entire first panel. At this point I'd like to call the next six witnesses. We will take a break after these witnesses have had the opportunity to speak. I'd like to call Emanuel Figueroa, Sara Larson, Joseph Frewer, Annie Chau, Marissa Knodel, and Allison Bacon, please.

All right. Well, I can see there aren't six people up there. Clever. Emanuel Figueroa. We will move Mr. Figueroa to the end. Sara Larson. Ms. Larson likewise.

Joseph Frewer. Thank you, Mr. Frewer.

MR. FREWER: Good morning. My name is Joseph Frewer. I am a college student originally from Houston, Texas. I am in school at Pomona College in Southern California.

I am speaking today as a public citizen, also as a volunteer for the Sierra Club for the summer. Primarily, I am here because I'm concerned about global warming. As you've heard multiple times, the scientific conclusion is that to mitigate the worst effects we really need to cut our carbon pollutions by 80 percent by 2050.

And many of us are agreed that the best way to do this is by utilizing every tool we can. We've got to look at every aspect of our economy, not only the transportation sector, which is addressed here, but many other parts, industrial -- I don't need to go into them.

But this 20 percent is part of a bigger picture, and we must take that into account when looking at a global solution. Just because it's 20 percent doesn't mean that it's any less important and that it can be ignored, just because when you look at in the context of 100 percent global emissions picture, it doesn't seem that important as it is.

NHTSA's draft environmental impact statement fails to analyze the benefits and reduction for fuel economy standards in the proper context because it is going by the bare minimum. As we have said, I'll try not to go into the same statistics that we've heard, but 31.6 miles per gallon, the bare minimum, just won't cut it. There are already cars being released that promise to offer more than 31.6 miles per gallon of gasoline.

We have people wanting to better the environment, wanting to save money, wanting to reduce our dependence on nations that are not always stable, not always friendly. And I'd say conserving our gas is a lot better solution than trying to drill on our soil, for instance, because the problem with gas prices is a demand problem.

China and India and other developing nations are not going away. And as our oil consumption stabilizes, they're still growing at an exponential rate. And so what we can do to conserve gas right now not only will help us use less, it will help us decrease the price of a gallon of gas. But it will also, the technology we develop and our car makers develop in cutting down how much fuel our cars and trucks use can be transferred to other countries, and can help solve the global warming problem on a scale greater than our 20 percent transportation sector economy.

So as I said, the current estimation of the price of a gallon of gas, which is, I think $2.25, not counting inflation in 2016, is unrealistic. I mean, we all prices right now, while they've been fluctuating, they're not going to drop back down to what they used to be. They are definitely staying above $3, and I think that's what most economists are saying. So we need to at least take this into account when coming up with what our standards need to be.

And I'd say a personal reason why I'm here, I go to college in a suburb of Los Angeles. I had an internship in West LA. I'm from East LA. And it's a commute that probably a couple million people do every day. I did it twice a week and it turned out to be probably a quarter tank of gas every day that I drove to my internship. And as a student, I could barely afford that.

Luckily I was subsidized by my college, but I can't imagine having to pay for groceries and having to pay for dependent children and paying this much money for gas, especially people who are driving cars that are 10-15 years old. We need to start coming up with solutions preemptively so that by the time 10 or 20 years roll around, their 15 or 20 year old car won't be as bad as the car I was driving, for instance.

So for commuters, for grocery prices, for many reasons I can see as a student, and I'm concerned about for the future, we really need to up our standards. We need to take into account more factors than just this transportation sector. But we need to recognize that the transportation sector is essential and part of a bigger solution to combat global warming, part of a solution to save our economy, which right now is not looking so good, obviously.

So that's all I have to say. I urge you to take another look at your draft environmental impact statement, and thank you very much.

MR. KRATZKE: Thank you, Mr. Frewer. Annie Chau, please.

MS. CHAU: Good morning. My name is Annie Chau, and I'm a representative from U.S. Public Interest Research Group. On behalf of U.S. PIRG and our federation of state PIRGs representing over a million citizens in America, I urge the National Highway Transportation Safety Administration to strengthen CAFE standards, and to follow the Consumer Federation of America's recommendation.

That means first, correcting the conceptual flaws in the agency's model, and establishing clear tests and analytic procedures to evaluate standards.

Second, setting the 2011 to 2012 standards at a substantially higher level than previously proposed. And third, rescinding the 2013 to 2015 standards, which are based on incomplete information.

Consumers in America want, need, and deserve real and lasting solutions that improve the fuel economy of our cars and trucks, and reduce our nation's energy consumption.

The way we travel is a big part of our energy crisis. Two out of every three barrels of oil that America consumes each year are used to fuel our cars and trucks. Furthermore, our nation holds just 3 percent of the world's proven oil reserves, yet we use 25 percent of the world's oil.

Our dependence on oil has become increasingly painful for American families. We are now spending close to $100 a week on gasoline costs alone. This makes household spending on transportation the second highest expense for the average American family, more than food, clothing, and even health care.

NHTSA unrealistically predicts gasoline prices to be only $2.25 per gallon in 2016. But Americans are already paying nearly twice as much today. U.S. PIRG research from squandering to stimulus shows that in the last five months American families have spent the entirety of their stimulus checks filling their tanks, while the cost of gasoline skyrocketed more than 40 percent.

Rather than boosting our faltering economy, the economic stimulus money went straight to big oil companies like Exxon/Mobile who are now reporting record breaking profits.

The agencies of the federal government must serve the people and find long term solutions for our energy crisis. At U.S. PIRG we believe in solutions that allow

Americans to drive less, such as consistent and innovative investment in public transportation. The most fuel efficient trip will be the trip not taken.

Americans are driving less. We as a nation traveled fewer miles in the last year for the first time in over two decades, and we are taking public transportation in record numbers across the country.

Many Americans do have to drive, though, and we must make those trips more fuel efficient by improving and modernizing our cars and trucks. This should be a top priority for the industry, our nation's leaders, and our federal transportation agencies. Forward thinking today will save us energy for tomorrow.

We fully support the comments of the Consumer Federation of American and we agree that NHTSA has failed to prioritize the need to conserve energy, has undervalued the benefits of increased vehicle fuel economy, and has kept standards too low for too long.

By ignoring a critical situation that is facing our country, the rising cost of gasoline, and our limping economy, every American is burdened when the fuel economy of our cars and trucks falls short.

We strongly urge this body to follow the recommendations of the Consumer Federation of America. Our nation's energy future depends on it. Thank you.

MR. KRATZKE: Thank you, Ms. Chau. Marissa Knodel.

MS. KNODEL: Good morning. My name is Marissa Knodel, and I grew up in Rochester, Minnesota, and now go to school at Dartmouth in Hanover, New Hampshire.

I am having an extraordinary opportunity to work with a professor there in the creation of an international NGO that can better represent the interests of South Pacific Island nations in negotiations concerning global warming and climate change.

This is an issue of environmental justice, since these countries have contributed the least to global warming, and yet given their size, location, geography and lack of political power, will suffer the most from global warming.

The highest point on many of these islands is only a few years high. Now, with global warming causing sea levels to rise, and increasing the magnitude and severity of tropical storms, many of these nations already have agreements with the governments of New Zealand and Australia to evacuate their entire populations with the expectation that their homes will be under water within the next 50 years.

The United States, on the other hand, represents only 4 percent of the world's population, uses one quarter of the world's oil, and contributes the most to global warming pollution to the atmosphere.

The United States is very good at outsourcing the environmental responsibility for the energy that it uses, and the pollution that it creates. But now that Americans are starting to feel the financial burden from our addiction to oil through higher prices at the pump, and the environmental burden through storms like hurricane Katrina, the oil spill in the Mississippi a little over a week ago, and the threat of off shore drilling, we realize the consequences of oil dependence and are demanding change.

Oil companies have been reporting their second quarter earnings, and last week at $11.68 billion Exxon/Mobile earned the largest quarterly profit of any U.S. corporation ever.

Now, for those families earning less than $15,000 a year, oil expenses represent 10 to 13 percent of their annual income. This, too, is an environmental injustice.

We have the ability to both reduce the amount of greenhouse gases we put into the atmosphere, and move away from oil and other fossil fuels. About 69 percent of our oil consumption, and one-third of our global warming pollution comes from the transportation sector.

In order to reduce oil use and reach the goal of an 80 percent reduction in greenhouse gas pollution by 2050, we can increase fuel economy standards, make sure hybrid and plug in electric vehicles are available and affordable, and improve public transportation.

Increasing CAFE standards to 35 miles per gallon by 2015, instead of waiting for 2020 as currently required save 300,000 gallons of oil per day by 2020, which is equivalent to keeping 280 million metric tons of carbon dioxide out of the atmosphere.

Not only is global warming and the oil addition that contributes to it an environmental injustice for South Pacific nations, keeping CAFE at a minimum of what is possible is an injustice for Americans trying to live out their daily lives, and for all those who believe in a future of clean, renewable energy, cars that can get 100 miles per gallon, and a healthy, safe environment for everyone everywhere. Thank you very much.

MR. KRATZKE: Thank you, Ms. Knodel. Allison Bacon. All right. Ms. Bacon will be moved to the end of the program, too. At this point, I think we will take a 15-minute break. Can I ask you to come back at 10:40 and we will start up again. Thank you.

(Whereupon, at 10:29 a.m., a brief recess was taken.)

MR. KRATZKE: All right. If we can, we would like to get started now with the remainder of our morning session. Available slots at the table are for Reverend Dr. Mari E.

Castellanos, Matthew Du Pont, Barry Bernsten, Pamela Woodward, Eli Hopson, Henry Desilva, Caroline Keicher, Christina Marie Yagjian, Lois Dean, D.C. Amorison, Julie Locascio and Kara Miamosi. And I would like to begin with Reverend Dr. Castellanos. All right. We'll come back. Matthew Du Pont? Thank you, Mr. Du Pont.

MR. DU PONT: Hi. Thanks for taking the time to listen to me today. I'm Matt Du Pont, a college student, and I'm a citizen.

Now, I'm not an expert on environmental issues, and anything I could say about those realistically is going to be said better and with better sources by someone else that has spoken today or will speak after me. So I'll only take a few minutes of your time and make a very simple speech about an issue that wouldn't require much work on your part, but is very important. And that's the accessibility of this EIS report to the general public.

Now the speech structure is very simple. I'm going to show you firstly that you will find this issue important. Secondly, you have a duty to make that EIS report transparent to the public. And finally, that it's currently failing to do so.

And this leads to the conclusion that simply by throwing on a very accessible, readable, lower level two to three page summary in addition to what you already have in this report, you can make this much more accessible to the public who demand this information.

So first of all, I think it's not too controversial that people find this issue important, after all this directly impacts global warming which according to a March 2006 time pole, 88 percent of American's find relevant for future generations.

But more importantly for our purposes here, 49 percent of Americans think that this is one of the issues that is very important to them, one of the issues that they are going to find out of their way to actually find out information about, instead of just reading it in the papers. So we know it's important, we know it's important to Americans.

And secondly, it's very noncontroverial that the EIS is supposed to inform the public, not just policy makers. People look to the CEQ regulations governing the EIS creation, which cite a purpose of the EIS as "to encourage and facilitate public involvement in decisions which affect the quality of the human environment." And they are also several clarity and brevity requirements meant to make them more accessible to the public.

So we've got this demand for information. We've got this EIS with a burden to show the public how that information is being used. It sounds pretty good. But in reality right now, this particular environmental impact statement is failing to make itself accessible to the public.

I mean, first of all there is a length. Now, the CEQ guidelines say that reports should be less than 150 pages in most cases, in very special cases under 300. So if I, as an average citizen who is not getting paid to deal with these issues, am confronted with this 414 page monstrosity, it's highly likely I'm going to read more than the summary, if I read anything at all.

But this brings us to the second problem. Even if I got to that summary, the very first sentence in the forward, I am confronted with no less than nine acronyms, probably six of which I don't know. It's just not very encouraging for me as an average person trying to vote correctly, to advocate policy, to be able to read this report, although maybe it's applicable to policy makers. But I, you know, as just a regular citizen, it's hard for me to get through.

So, and it doesn't get much better from there on in because the summary assumes knowledge of a lot of things. It assumes that I know why rising sea levels are bad, which admittedly is explained in the report, but I'm probably not going to go to page 270 or wherever that's explained, if I'm not grabbed in the beginning.

And so we have this inaccessibility, and I think it's a huge problem. The citizens who are interested but don't have a career as a nonprofit policy wonk or an auto industry lobbyist are simply not going to read a 414 page report, or even a 25 page summary.

And this brings me to the point of my speech, something you could do very easily. It's not a solution, but it's certainly a step in the right direction. By simply providing a short jargon free summary, say just two to three pages long, in addition to what's already in the report, specifically labeled, for average citizens who don't know as much about the issue, you can allow people to make meaningful conclusions from this EIS, to be able to read it and perhaps talk to their neighbor about it, or talk to their Congress person. But whatever they do, advance a stated cause in the mandate of the EIS, to advance public discourse.

Now, because frankly, your job as the EIS author is not just to help policy makers, it's to interest me, an average citizen. And I stand before you today, right now, as an intelligent environmentally conscious citizen, the exact target audience for any EIS report. But because I and thousands of other people have no interest in slogging through the dense prose that makes up most of this EIS, it's failing in its duty to provide information to the public.

And as such, I would please ask you to add in this and future summaries a very short, a short, more accessible,

tsh

clearly written piece that addresses the public. Thank you for your time.

MR. KRATZKE: Thank you, Mr. Du Pont. Barry Bernsten, please.

MR. BERNSTEN: My name is Barry Bernsten. I'm president of BG Automotive Group located in Philadelphia, Pennsylvania. We are building the first mass production facility in the world for the production and assembly of electric vehicles, a product that is now a necessity in the world, and not just an alternative.

First, I would like to thank NHTSA for giving me the opportunity to speak to this committee that appears to be interested in the public's opinion with regard to the environmental impact of the new CAFE rules. I might be one of the few people in this country that have read most of the 414 pages of the environmental impact statement with regard to the CAFE rules covering model years 2011 to 2015.

I must commend the team that prepared the document for their time commitment, but I do not commend them for their due diligence and their accuracy. They clearly forgot to include the direct human health care costs, as well as the quality of life issues in their report.

Every morning I turn on the news or I read the paper and I see the air quality report in the Philadelphia region. Needless to say, this report peaked my curiosity. After doing some further research, I found a government website called air now.gov that provide daily reports on the air quality around our nation.

I was shocked to see that their were color coded air warnings for the air quality based on where you reside in North America. The government calls it the AQI, air quality index. These are color coded, similar to our terror alert index, or terror alert codes.

Also, I noticed that there were existing real time alerts in our country today, this past weekend, that were orange, being unhealthy for sensitive groups, and even red, a strict statement of being just unhealthy to breath.

After further research on air quality elements, I found that approximately 17 million people have asthma in our country, of which 5 million are children, and one of them spoke with you here today.

What I did not read in the 414 pages of the environmental impact statement as it clearly relates to air quality, was the direct associated cost with the 1.5 million emergency room visits for asthma patients, or the $14 billion in health care costs related just to asthma related illnesses.

The report also did not include the direct costs associated with emphysema and/or chronic bronchitis due to

CO2 emissions or greenhouse cases. Why didn't the environmental impact statement consider the direct health costs associated with their study, and the quality of life costs associated with such an important report?

Saving billions on oil, reducing greenhouse gases, slowing global warming is a given. We are reminded and educated every day. This you covered in the report.

According to another government site from the National Institute of Environmental Health Sciences, "according to the Environmental Protection Agency's estimates on air pollution, the commitment to new air quality standards, and cleaner air will prevent 23,000 premature deaths in America. 1.7 million cases of asthma attacks will not occur. And 67,000 new cases of acute an aggravated bronchitis can be limited.

All Americans should be outraged at this agency's report, that it did not include the quality of life costs, and the billions of dollars of direct health care costs as it relates to their analysis as a result of the CO_2 greenhouse gases referred to in your report.

More Americans are not only walking and riding bicycles to work, but we now have to tell our children when and when not to play outside.

Instead of taking the latter issues into consideration, the study includes an environmental impact equation, the net cost benefit or detriment which includes input from the automotive companies and the lobbyists.

The auto companies complain that it is not economically feasible to produce more fuel efficient vehicles due to their retooling costs, and their extensive health care costs. The DOT demands that the industry finds themselves in a situation where they are negotiating with the automotive companies and the automotive lobbyist, which we don't understand as an American public.

This is not the auto industry's decision. This is your decision, NHTSA's decision on where and how to set these standards. The bottom line is that we all know of the strongest CAFE rule will lead to the strongest environmental impact for the air quality and the quality of our lives.

I thank you for the opportunity to speak to you. Thank you.

MR. KRATZKE: Thank you, Mr. Bernsten. Pamela Woodward, please.

MS. WOODWARD: Good morning, and thank you for giving me the opportunity to speak today. I am a local resident. I live in Silver Spring, Maryland, and I've never spoken in front of any type of board before, but I felt that this was a very important issue, one that has a very strong, that I have strong feelings for, so I decided to do this.

I'm an avid world traveler who likes to leave the bustling city for relatively wilderness areas, such as, I've traveled to Antarctica, to the Amazon, to the Galapagos Islands.

And I've seen some of the effects of global warming during my travels, and in particular in Antarctica where there are massive amount of ice breaking off from the ice shelf.

And I think it is important for us, as a country, to realize our responsibility in preserving the wilderness areas, and this includes getting away from our dependence on oil, both foreign and domestic. It also includes expanding existing technologies, such as hybrid technologies, electrical vehicles, rather than looking to drill in unspoiled wilderness areas like is being considered right now.

In addition, I've lived in foreign countries where the emission standards are negligible at best. And as was referred by the previous speaker, I have been subject to chronic throat and bronchial infections due to inhaling air from strong exhaust.

In addition, I've lived in parts of this country, this area and in Northern California where I can feel, taste, smell the air on days where it's code orange or code red. And I can feel it if I try to exert myself, I can feel the effects on my lungs.

In addition, a couple of years ago I was, I went to shop for a new car with my husband. And I wanted to get the most fuel efficient car possible, both from a cost perspective, since we're paying $3 to $4 dollars a gallon in gas, and also from an impact on the environment. And unfortunately, our choices were severely limited, due to the lack of availability of such vehicles. We couldn't even test drive a Toyota Prius because none were available, they were so popular.

I'm here today to ask you to really consider the environmental impact of any standards you set, and to take into account the quality of life for both the current population as well as future populations of this country and the world.

You need to use realistic gas prices, prices that are, that equal the current average, which is much higher than the $2 plus range. It's in the $4 plus range. And you also need to understand how many people would be interested in buying fuel efficient vehicles, were they both accessible and affordable.

The technology exists. There are companies that are using successfully, and other companies should be encouraged to develop the technology even further. Thank you very much for your time today.

MR. KRATZKE: Thank you, Ms. Woodward. Eli Hopson, please.

MR. HOPSON: Hi. First I'd like to thank NHTSA for holding this hearing, and for giving us the opportunity to offer comments on the draft EIS.

I'm the Washington representative for the Clean Vehicles Program of the Union of Concerned Scientists. UCS is a leading science-based nonprofit, and we've been working for a healthy environment and a safer world for over 30 years.

The topic of this hearing the, environmental impact fuel economy standards could not be more urgent. Put simply, global warming is the single largest environmental threat facing the country and the world today. $4 a gallon gasoline is strangling our economy.

But within these threats are varied opportunities. Increasing fuel economy standards will reduce global warming pollution from our cars and trucks. It will cut America's oil addiction, and it will save consumers billions.

At the same time, the investments we make in our domestic auto industry will strengthen our economy and our ailing domestic auto makers as we help them build the vehicles that are essential to avoiding the worst impacts of global warming.

There are two primary flaws in the draft EIS that must be fixed in order to give the public a true idea of the potential environmental impact of this rule. First, the fuel economy standards are being measured for their global impact, even though they only affect a portion of all manmade sources of global warming pollution.

Second, the methodology of a rule upon which this EIS is based is fundamentally flawed and improperly limits the potential environmental benefits from increasing fuel economy.

But first the scope. If we are to avoid the worst impacts of global planet change, our nation and the world must adopt a target that will keep global temperature from rising more than 2 degrees C above pre-industrial levels. That means stabilizing the concentration of global warming pollutants in our atmosphere at no more than 450 parts per million CO_2.

Analysis by UCS shows that one part of achieving that goal means the United States must cut its global warming pollution at least 80 percent compared to emissions levels in 2000. In addition, our analysis indicates that in order to effectively achieve such a long term goal, we have to start now. We have to reduce our pollution 20 percent below 2000 levels by 2020 and at least 50 percent below by 2030.

The need for these long term targets and immediate action is not effectively covered in the EIS, and the cost of inaction of the size of this challenge also should be better reflected.

Importantly, there is no single silver bullet that will dramatically cut U.S. global warming pollution, and no single sector will be able to carry the full burden. Instead, we're going to have to do a diverse set of policies that's going to cover every sector comprehensively.

Transportation, including the cars and trucks consumers drive every day will have to play a significant role in meeting this 80 percent reduction, minimum, and all options for cutting pollution from transportation must be on the table.

Unfortunately, the analysis done by NHTSA only presents the reductions from the fuel economy rule in the context of their direct impact relative to all manmade global emissions, rather than just the emissions from our cars and trucks.

Because higher fuel economy standards alone won't solve global warming does not discount the fact that they are a vital, necessary part of the solution. By stating them in terms of their percent reduction from the sector, approximately 30 percent, rather than a percent of world reductions which is .8 to 1.1 percent, according to the draft EIS, the value of the fuel economy in reducing global warming pollution and helping us meet those near term targets will be clear and less misleading to the public.

NHTSA's approach to the EIS is like arguing that we shouldn't worry about smoking in 16 year olds, because they're only a small percentage of the smoking population. Instead, this argument could be used against all persons in the sector to say, well, global warming is such a big problem, we can't use it in here, we can't use it here. We shouldn't deal with it at all. Instead a more comprehensive approach needs to be looked at, and the EIS reflect that need.

The second problem is with the announcements that the rule is based on. A recent UCS report indicates that auto makers can cut cost effectively their fleet wide average fuel economy of cars and trucks and improve it to 42 miles per gallon by 2020, and up to 50 and more than 50 by 2030, with a modest 25 percent penetration of hybrids by 2020.

The recent proposed notice rulemaking actually assumed that hybrids wouldn't be on the road until 2014. Let me just reiterate that. Despite the fact that there are more than 1 million hybrids on the road today, despite the fact that the Toyota Prius is the ninth best selling car in America, the announcements that NHTSA used assume hybrids won't be on the market until 2014.

People are not sitting around waiting for a hybrid to show up on a dealer's lot in six years. They're on six month waiting lists, as we heard today, because they are already that popular.

There's a number of other flaws in the base analysis that have been covered today, but I just want to point out one last one. The value of carbon dioxide that NHTSA used, they assume $7 per ton. Carbon dioxide is currently trading in the European futures market at $40 per ton.

The other list has been mentioned, but I just want to summarize and say your own analysis showed that if you use a more realistic gas price, or switch to an analysis based on total benefits, each of those would allow us to reach Congressionally mandated minimum five years earlier, so 35 miles per gallon by 2015, and would help us get a head start on solving our global warming problem. Thank you.

MR. KRATZKE: Thank you, Mr. Hopson. Henry D'Silva, please. All right. Caroline Keicher.

MS. KEICHER: Hi. Good morning. Thank you again for having us today and allowing us a chance to talk about this draft environmental impact statement.

My name is Caroline Keicher, and I am here because I am incredibly concerned about the impacts of global warming in this country, because I think that NHTSA has a responsibility to put into place the strongest fuel efficiency standards possible to help us reduce our global warming emissions from vehicles.

The debate is over on a time to change. The scientists and the American public have come to the same conclusion. It's happening now, and we are already feeling the vast repercussions. We must act immediately if we are going to stave off the worst effects.

The reports on climate change that pour in daily no longer focus on predictions for the far future, but on the consequences that we are already experiencing today, and how global warming will continue to disrupt our environment, our economy, and our very ability to survive if we don't act quickly to reduce our carbon emissions.

It's more important now than ever to curb our greenhouse gas emissions and to do our part to mitigate global climate change. The cost exacted on us if we do nothing is guaranteed to be worlds steeper than any possible cost prevention.

The scientists made it clear that to avoid the worst effects of global climate change, we must achieve 80 percent reduction in our emissions by 2050. This gives us approximately 40 years to get our act together, and we have no time to lose.

Unfortunately, there is no single thing that we can do, or single sector in our economy that we can cut to get us all the way there. We must instead start making manageable emission reductions from each single carbon emitting sector of our economy. And when considering the benefits of doing so, we must consider each reduction as part of the larger long term goal, both for the United States and globally. Each reduction that we fail to make in one area will have to come from somewhere else.

The most disappointing thing for me about NHTSA's draft environmental impact statement is that it fails to analyze the benefits of greenhouse gas emission reductions from various fuel economy standards in the proper context. Not surprisingly, when NHTSA tries to determine the global warming impacts resulting in 2100 from various standards, 31.6 miles per gallon in 2015 versus 35 miles per gallon, there isn't statistically much of a difference.

And this isn't surprising. It also doesn't mean that raising fuel economy standards faster will not have a significant impact in our struggle to reduce global warming pollution.

Emissions from the transportation sector in the United States account for roughly one-third of our greenhouse gas emissions, with cars and light trucks coming in at about 20 percent. That's a fairly large chunk of our contribution to this global problem.

So what is the proper context? How do we consider these various CAFE increases? Globally the science has called for long term reductions of emissions of about 50 percent for the entire world by 2050. Here in the U.S. as an industrialized nation that accounts for nearly a fourth of world carbon dioxide emissions, this translates for us into about 85, 80 to 95 percent needed reductions below 2000 levels by 2050.

In the short term this is going to mean that we need to reduce our emissions between 25 and 40 percent by 2020, so a much sooner time line. This is a much bigger number, and this is what's most relevant with these new CAFE increases.

If we're going to evaluate how an increase in corporate average fuel economy affects global warming, this is the target that we should be focused on, not some obscure number in 2100.

In addition, the proportion of emissions saved is much less important than the total cumulative carbon savings. The front end reductions are more important and have more cumulative impact than later emission reductions.

Taking this into account, it seems even more obvious that NHTSA should set new fuel economy standards to reach 35 miles per gallon by 2015. Not only is this standard economically and technologically feasible when a more accurate gas price is used, but it gets our cars and light trucks traveling an average of 35 miles per gallon five years sooner, the cumulative carbon savings of which is anything but insignificant.

NHTSA has proposed standards for both cars and light trucks in response to the energy independence and security act's mandate to achieve a fleet wide fuel economy average of at least 35 miles per gallon by 2020. NHTSA proposes to raise fuel economy of cars and light trucks to a combined average of 31.6 miles per gallon for model year 2015.

While this increase is more than half of what is required to meet the floor set by the EISA, NHTSA fails to take full advantage of the fuel saving technologies, and fails to fully and fairly evaluate the benefits of greenhouse gas emission reductions.

NHTSA must reconsider the proposed standards and use its statutory authority to meet the urgent need of the United States to reduce carbon emissions, conserve oil, and meet the growing demand of American consumers for vehicles that go farther on a gallon of gas. Thank you so much for your time.

MR. KRATZKE: Thank you, Ms. Keicher. Christina Marie Yagjian.

MS. YAGJIAN: Good morning. My name is Christina Yagjian, and I am here today as a concerned citizen. I'd like to start by thanking NHTSA for holding this hearing and for giving me the opportunity to speak today.

I'm here because I'm concerned about the effects that global climate change will have in my lifetime on my life and the lives of those that I care the most about, if we don't take the most rapid and comprehensive measures available to us to reduce global warming emissions now.

This draft EIS takes a step in the right direction, but fails to go the extra miles necessary to properly face the problem at hand. NHTSA's draft environmental impact statement fails to analyze the benefits of greenhouse gas emissions reductions from fuel economy standards in the proper context.

As a young professional with baby boomer parents approaching retirement, and hopes of one day having a family of my own, I'm concerned about the effects that climate change will have on the elderly and future generations.

My father, who lives outside of Austin, Texas, a state which is already hot and dry, has begun to see increased droughts. This summer alone he has had to purchase two truckloads of water for his home, which is not on the city's water system, whereas last year he only purchased one.

The IPCC estimates that average temperatures in Texas will rise 5.85 degrees by 2100 if global warming continues unabated. I am concerned about the effects that these temperatures and weather conditions will have on my father as he gets older and his health is more vulnerable.

As you have heard this morning, the debate on climate change has ended. And we see issues such as increased droughts, as I mentioned -- as we see issues such as increased droughts, as I mentioned, in Texas, we see that we are feeling the effects of climate change today.

The science has made it clear that to avoid the worst effects of global warming, we must achieve 80 percent reductions in global warming emissions by 2050. As cars and light trucks account for 20 percent of the country's global warming emissions, the single biggest step that we can take in this country to reduce global warming emissions, save consumers money at the gas pump, and reduce America's dependence on foreign oil is to make our cars and light trucks go further on a gallon of gas.

It has never been more important that we take the strongest measures available to us to curb global warming emissions, and to do our part to mitigate the effects of global climate change.

NHTSA's draft environmental impact statement fails to analyze the benefits of greenhouse gas emissions, emission reductions from fuel economy standards in the proper context. As I mentioned, we know that emissions from the transportation sector account for roughly 20 percent of the country's global warming pollution.

The EIS projected decreases in emissions rising from increased fuel economy standards are analyzed as a proportion of combined global carbon emissions. This figure is more clearly evaluated when presented as a proportion of the current 20 percent of domestic emissions.

An additional issue I would like to highlight is in this draft environmental impact statement is that NHTSA has arbitrarily picked 2100 as a time line for measuring the success of today's carbon reductions. A nearer term goal would help to ensure that the transportation sector does its part to achieve the goal set by the scientific community of 80 percent reductions by 2050.

In the EIS NHTSA presumes that fuel economy standards stop increasing after 35 miles per gallon in 2020. In order to properly evaluate carbon savings through 2100, NHTSA should extrapolate a curve of increasing fuel economy standards that continues to increase to 2100 at the same rate of increase as between 2011 and 2015. In order to ensure that we take the strongest measures available, NHTSA must do its part. It must begin by evaluating fuel economy standards in the correct context.

I am concerned about the effects of global warming that our planet will feel in my lifetime if our country does not show leadership and take the single most important step in reducing our carbon emissions, which is to reduce greenhouse gas emissions from our transportation sector as efficiently and effectively as possible.

In order to ensure that we take the strongest measures available, NHTSA must do its part. They must begin now by evaluating fuel economy standards in the correct context and setting fuel economy standards at the maximum feasible level, at least 35 miles per gallon by 2015. Thank you for this opportunity to testify.

MR. KRATZKE: Thank you, Ms. Yagjian. Are there any of the panelists who could come to the table who have appeared, Ms. Dean, Dr. Amarasing, Ms. Locascio or Ms. Massey, here? Please.

MS. LOCASCIO: My name is Julie Locascio. I have lived in several different cities, but have resided in Washington now for seven years. I have worked as both a planning consultant and an attorney. And I have extensive education and experience in environmental law, policy, and planning.

When I learned that NHTSA was using a CAFE cost benefit analysis based upon a projection that gasoline prices will be well below $3 a gallon in the next two decades, I was shocked. That is why I am testifying today.

I am trained as a planner to do cost benefit analyses. The NHTSA has been directed to regulate the private sector towards a 35 mile per gallon standard or better, i.e., a maximum feasible fuel economy. NHTSA is permitted to balance the cost of improving fuel saving technology against the benefits which will accrue by doing so, including the environmental benefits of reduced gasoline consumption.

The environmental benefits include reduced oil drilling on American land and off shore territories, reduced ground level air pollution emissions, and reduced carbon dioxide contribution to global warming.

Nonetheless, many consumers will look first to the impact on their own finances in assessing the value of increased CAFE standards. A higher priced vehicle will be worth the extra cost to the consumer, if the consumer gets higher fuel efficiency. But if NHTSA is saying that such a consumer will only save about $2.50 for every gallon of gas longer needed, well into the next two decades, this analysis is completely distorted.

As everyone knows the price of gasoline at the pump is current hovering around $4 a gallon, and one would be hard pressed to find a cross-section of economists who would predict that the price of gasoline is going to drop back down below $3 a gallon in the two decades to come.

Indeed, even Guy Caruso, EIA administrator has testified that the CAFE cost benefit analysis should be using an oil price between $2.96 and $3.63 per gallon. I don't see how NHTSA can ignore the expert recommendation of the man responsible for ensuring that the statutory and regulatory requirements for legally performing the environmental impact assessment are fulfilled.

I'm not going to use this testimony to explain to you the repercussions of your actions on global warming, because I think you already know them. I'm not even going to use this testimony to talk to you about the hundreds of thousands of urban children who cannot go outside to play during the most heavily polluted days of the year. I think you know that too.

What I am going to ask you to do is to stand up for common sense economics and state of the art science. I am going to ask you to stop worrying that this administration is going to fire you for doing the right thing.

I am going to ask you not to tow the line in promulgating regulations that make no sense, and which if promulgated will only lead to litigation and a lengthy delay until a federal court orders the administration to comply with the law.

In short, I am asking you to make a stand because we are all in this together, and none of us wants to be explaining to future generations why we continue trashing the air we breathe, when we all knew better. The more we refuse to pay today, the more we will all be paying tomorrow.

If realistic fuel costs are used in a CAFE cost benefit analysis, NHTSA could set mile per gallon standards high enough to be the carbon equivalent of taking an additional $10 million cars off our roads. Please do the right thing. Thank you for listening to my testimony. May I submit my written testimony also?

MR. KRATZKE: Thank you, Ms. Locascio. We have five more people who we had planned to have speak before lunch. If any of them are present, I would invite them to come up to the tables. Dennis Chestnut, Tara Morrow, Sarah Karlin, Heather Moyer, and Larry Menkes. Dennis Chestnut? No. Tara Morrow. Ms. Morrow.

MS. MORROW: Thank you and good morning. Thank you for the opportunity to speak today on this DEIS. My name is Tara Morrow, and I'm on the staff of Greater Washington Interfaith Power and Light. We are one of 28 interfaith power and light organizations across the United States, a growing movement of people of faith responding to global warming.

When religious people talk about responsible stewardship of our resources or care of the earth, it is toward abundant life for future generations that they measure the costs to their own lives.

As you set standards to meet the energy independence and security acts mandate to achieve a fleet wide fuel economy outreach of at least 35 miles per gallon by

2020, may you remember that 35 miles per gallon is a minimum, and future generations will applaud us for our boldness in implementing what is technologically feasible, or wonder how we lacked the creativity and will to respond to global warming and the challenges of energy security.

I did study physics in college before attending seminary, which does help me get through the statistics and tables of the DEIS. But I am here today as a person of faith, in particular, greatly concerned about the impact energy policies and activities resulting in increased global warming emissions have upon the poor and vulnerable.

As was demonstrated during the aftermath of hurricane Katrina and around the world in recent months with increased food prices, quantifying the impacts of global climate change is not simple, and will only increase in value as we more fully grasp its consequences.

The debate about whether climate change is real or caused by human activity is over. And as I witnessed from first hand accounts during a recent trip to the Philippines, the effects are already taking a toll upon our world.

While I was glad to see that the DEIS does assign a dollar value greater than zero to CO2 reductions, I ask you to take another look at the value range and price carbon more accurately given the most recent analysis, as others have referred to here today.

The costs of global warming exacted on us, or more accurately on our children and grandchildren, and generations to come, if we take only token action now is sure to be steeper than any costs that we will incur now.

Another matter for closer examination in the DEIS is the estimate of the price of gasoline used to determine what is cost effective. Many here have already referred to this, but I, too, was quite shocked to see an assumption of only in the $2 range for 2016, that's in terms of 2006 dollars, and it does seem quite unrealistic given current realities, at least given what I paid myself in my own Ford Focus yesterday on my way back from a family reunion in Pennsylvania, which I had bought because it got pretty good mileage at the time. But with the price of gasoline, I have to think about what trips I'm going to make.

When higher projections of gas prices are used, then significantly higher standards are technologically feasible and economically practical.

Given the recent soaring gas prices, we are seeing a change in the market by consumer demand for vehicles with greater fuel economy. However, I think the American people are ready for bold action, at least my generation is, and moving forward will take more than responding to market research.

It takes full measure of the costs to us if we do not take action or take only very modest action. Costs which the DEIS begins to address, but I hope will be more fully incorporated when the final fuel economy standards are issued for passenger cars and light trucks for 2011 to 2015. Thank you for your time.

MR. KRATZKE: Thank you, Ms. Morrow. Sarah Karlin. Heather Moyer.

MS. MOYER: Good morning. Thank you for having this hearing. My name is Heather Moyer. I'm here as a concerned citizen. Thank you for holding the hearing.

I just want to say, as I watch people struggle to pay higher gas prices and argue consistently over whether we should be drilling for more oil, I am continually frustrated by our government's seeming lack of appropriate action in trying to address these issues, especially when addressing these issues in a smart way can not only save Americans money, it can also address our addiction to oil and fight global warming.

And I know that we as Americans must also take personal responsibility when it comes to helping the environment and driving smart and finding solutions to global warming. But it also falls upon us to urge our government to take the major actions that can widely address these sorts of problems.

The government must take actions, and if you are waiting to hear from Americans to tell you to do something, well, here you go.

As others have said, the debate over climate change is done. People agree. And we are already feeling repercussions. We're no longer talking about far away possibilities. Things are happening right now. As a former reporter who covered disasters, I saw many of these situations up close and personal. And we must take action now.

The costs exacted on us if we do nothing now is guaranteed to be far worse than any possible cost of prevention.

Although there is no silver bullet to get us to an 80 percent reduction in carbon emissions by 2050, the single biggest step we can take in this country to reduce our global warming emissions, save consumers money at the pump, and reduce our dependence on foreign oil, is to make our cars and trucks go farther on a gallon of gasoline.

The technology exists today to safely and cost effectively make all passenger cars and light trucks reach a fleet wide fuel economy average of at least 35 miles per gallon by 2015. Taking this step will achieve the goals of the new fuel economy law, and is most pertinent to this hearing, will greatly reduce the global warming emissions from the transportation sector, which as you've heard others say, may currently make up 20 percent of our country's greenhouse gas emissions.

And again, as others have said, I also was surprised and shocked to see the proposal assuming that future gas prices would be only $2.25 in 2016 using 2006 dollars. I found that shocking and saddening, and also laughable. And I urge you to use realistic gas prices. We know, I mean, again, we talked about cars, I drive a '95 Saturn. It still gets really great gas mileage. It now costs $40 to fill up.

NHTSA's own analysis shows that between 2011 and 2015 significantly higher standards are feasible and economically practical when higher gas prices are used. NHTSA's final rule should be, at a minimum, consistent with the analysis provided in the preliminary impact analysis that accompanied this proposed, this notice of proposed rulemaking.

When it comes to oil savings, the U.S., our increased global warming emissions from vehicles and growing oil dependence put our entire country at risk. We see this daily as billions of dollars flow out of our economy to pay for oil, while the reports on global warming impacts continue to flow in. It is time to put existing fuel saving technology to work by increasing fuel economy standards to the levels that reflect the maximum achievable standards for vehicles produced in 2011 and 2015.

And by the agency's own estimation, the proposed standards will save more than 54 billion gallons of gasoline over the five model years addressed in this rulemaking. Setting standards to at least 35 miles per gallon in 2015 would save an additional 22 billion gallons of gas.

America holds just three percent of the world's proven oil reserves, yet we use 25 percent of the world's oil and so clearly we cannot drill our way to oil independence.

NHTSA understands the importance of conserving oil. It makes every effort to undercut the oil savings that fuel economy gains can achieve for this nation. The high gas price scenario yield cost effective and technologically feasible standards that will help met the nation's need to conserve energy.

NHTSA should ensure that final standards are set using this value as a minimum. I urge you, you have the power to make rules that make such a huge difference, and I urge you to use that power and really take a stand and make a difference. Thank you.

MR. KRATZKE: Thank you, Ms. Moyer. Mr. Menkes. All right. At this point are there people here who were supposed to present earlier? Mr. Figueroa? Please.

MR. FIGUEROA: Hi, everybody. My name is Emanuel Figueroa, and I am from Puerto Rico. I'm sorry I was a little bit late. It's really difficult to get around this city. It's like everything looks the same for me.

So I'm here as a concerned citizen for gas prices and off shore drilling. I'm here because as a Puerto Rico citizen I don't have a voice, representation, or a vote on this administration, the Congress and everything that is happening with this government, but still manage to affect us in the small island in the Caribbean, the Commonwealth of Puerto Rico, that is 110 miles by 32 miles, and it has a population of 4 million people.

I am here also as a recent graduate that is making its way into the job businesses, and like I'm trying to like cope here with like my income and how much I pay for gas and other expenses that I have.

I'm here to the matter of change because you, as NHTSA, have the power and responsibility to enforce fuel efficiency standards of at least 35 miles per gallon. And this is the biggest single step that you can do to create a better world, and this will save a lot of gasoline, and this will save us a lot of money. And that's a really good thing.

I'm not an expert on global warming and energy issues. Because I'm a recent graduate, so I know a lot about the theory, but I don't know how it gets opined to our government and the policy making and the decision making strategies, but it doesn't make sense when we assume that the price of gasoline is $2 or $3, when we go outside and see the first, any gas station, doesn't matter if it's an Exxon, Mobile, Shell, any. You can choose your brand. You can choose the one that you like for your car, but it's way over $4 right now.

And it's really difficult when people are willing to pay more for their car to have a higher fuel efficiency, but it doesn't make sense in the numbers, because maybe the numbers that we're using are for old information or don't take into consideration the whole picture.

So I encourage you into NHTSA to actually take into consideration the correct price or re-evaluate what is going to be the price of gasoline in the future. Because when you plug in the right numbers into the formula that you use, it will make a lot of sense to have a higher fuel efficiency in our cars. Thank you.

MR. KRATZKE: Thank you, Mr. Figueroa. Mari Castellanos.

DR. CASTELLANOS: Good morning, and thank you for holding this hearing. I'm Dr. Mari Castellanos. I am a minister with the United Church of Christ, a denomination of 1.6 million people.

I speak not only on behalf of the church, but on behalf of the children of the church, for it is to them that we are accountable. It is their future which will be greatly impacted by the decisions you make. I charge you with their responsibility for their future.

35 miles per gallon by 2015, an 80 percent reduction of greenhouse emissions by 2050, is the minimum that we must achieve, a commitment to their future. It is God's creation. It is our children's future. In their name and on behalf of Andrew, Christopher, and Thomas, my grandchildren ages 10, 8 and 6, it is in their name that I request that you aim as high as you possibly can in reducing greenhouse emissions.

Thank you very much. We will carefully await your decisions.

MR. KRATZKE: Thank you Reverend Castellanos. Sarah Karlin, please.

MS. KARLIN: Good morning. My name is Sarah Karlin, and I am from Livingston, New Jersey. Thank you for the opportunity to testify. I am here today because I am concerned about the devastating impact global warming will have on this country and the entire world if we continue to stand by and casually ignore this impending crisis.

When I was younger, my parents would read to my brothers and me every night. One of our favorite books was the Little Engine That Could. Many of you probably remember this famous tale of a small engine whose hope and courage enabled him to pull a large train over a steep mountain.

Other larger engines refused, but this engine's famous motivating words, I think I can, I think I can, carried him over the hump.

Climate change is happening now, and if we don't respond quickly, global warming will continue to disrupt our environment, our economy, and our very ability to survive. We must act now to reduce our carbon emissions.

The science has made it clear that in order to avoid the worst effects of global warming, we must achieve an 80 percent reduction in greenhouse gases by 2050. At first glance, this may seem like a daunting task, but if we start now, and if like the Little Engine That Could, we believe we can, the U.S. can achieve the necessary emission cuts to prevent the most tragic impacts of climate change.

Yet NHTSA's draft environmental impact statement fails to analyze the benefits of greenhouse gas emission reductions from various fuel economy standards in the proper context.

Not surprisingly, when NHTSA tried to determine the difference in global ocean temperature rise in 2100, resulting from a 31.6 miles per gallon in 2015 standards, versus a 35 mile per gallon in 2015 standards, statistically there is none.

But this does not mean that raising fuel economy standards faster will not have a significant impact in our struggle to reduce global warming pollution. Emissions from the transportation sector in the United States account for roughly 20 percent of our country's greenhouse gas pollution, and as any projected decreases in greenhouse gas emission arising from increased fuel economy standards can never be greater than this, those reductions should be considered as a proportion of the 20 percent, not as a proportion of the entire planet's combined carbon emission. The latter simply overwhelms any measurable progress.

Adequate fuel economy standards can help the U.S. make a significant dent in our overall carbon emissions by 2050. Sure, other measures will need to be taken to meet the 80 percent reduction by 2050. But the transportation sector must play its part.

Imagine what the world would be like if every time history's great innovators faced a daunting task they simply gave up. We'd likely be living in a very different world. Where would the airplanes be, the computer, the internet. The list goes on and on.

Luckily the inventors of these technologies were not deterred by critics or nay sayers. Those with the power to solve global warming must follow in their footsteps.

The transportation sector won't fix all of our climate problem, but it does have a moral obligation to be part of the solution. NHTSA cannot afford to sit back and do nothing. Solving the world's climate crisis is possible if only we truly think we can. Thank you.

MR. KRATZKE: Thank you, Ms. Karlin. At this time, if there are no other speakers from the first 35, we will take our break for lunch. At the beginning I announced we were going to take lunch from 12:30 to 1:30, but since we're giving you extra time, if you could, we'd appreciate it if you'd be back at 1:00. That's about an hour and 15 minutes from now. Thank you, and we're looking forward to the rest of the witnesses. Thanks.

(Whereupon, at 11:44 a.m., a luncheon recess was taken.)

AFTERNOON SESSION

MR. KRATZKE: All right. Thank you. We are going to start our afternoon list of speakers. If I could, I'd like to ask the following group to come up to the tables at the front of the room. Jim Pierobon, Allison Forbes, Ron Halber, Rita Rodgers, James Keck, Rabbi Fred Dobb, Fred Teal, Alina Fortson, Matt Kirby, Jaafar Rizvi, Ben Schreiber, and Sarah Alderfer.

And I suppose with this I'd like to ask Mr. Jim Pierobon if he would like to start us in the afternoon session. Please, at the podium. Thanks. And just to remind folks, if you will, please state by stating your name so that our court reporter will have that clearly in the record. Thank you.

MR. PIEROBON: Thanks, Administrator Kratzke. My name is Jim Pierobon. I'm from nearby Silver Spring, Maryland, and I use, as I almost always do when I get to downtown, public transportation, the Ride-On bus system, and our wonderful subway system.

But not only do I take public transportation to get another car off the road, but it's another way of perhaps dealing with my personal frustration at the serious lack that I think we have in choices for very fuel efficient automobiles.

And I've worked as an energy writer for the Houston

Chronicle and a freelancer for the New York Times on a variety of energy issues going back to the 1980's. So, you know, I've had a lot of personal heart in this. And it's a privilege to come and speak to you here today.

And since then, I've been advocating for anything that can lead to a cleaner and significantly more energy efficient energy future of ours. But personally I'm appalled at how it seems to this layperson, with a fair amount of knowledge about energy markets and energy policy, how disconnected, if you will, the CAFE rulemaking seem to be, and the environmental benefits of significantly higher gas mileage standards.

You know, where possible, I'm a strong advocate for market oriented solutions. And you know, I would love to look to Detroit to be able to recognize the demand for more fuel efficient vehicles, especially as we've seen gasoline prices go up. But in this case, you know, with the growing challenges to our environment, it should compel, I think, you folks to put a much stronger value on higher mileage standards.

So I urge you, just to quickly conclude here, to use more realistic assumptions about how high future gasoline prices could go. And looking back on how high they've been this year. And I hope you'll recognize how fuel efficient hybrids, as one dramatic example, are becoming more valuable and how quickly and efficiently they can deeply penetrate, especially the consumer automobile market. Thanks for your time.

MR. KRATZKE: Thank you, Mr. Pierobon. I'd like to call Allison Forbes.

MS. FORBES: Hi, my name is Allison Forbes. I work with the Sierra Club in the D.C. area and just want to offer my personal comments today.

I have a friend with a Mercedes that's old enough to actually have this gadget on the dashboard that measures the mileage that she's getting, and it's not a new hybrid or anything like that. It's an old car that tells here, you know, how much she's getting for her money and her gas in the tank. And I know we've lost the consciousness of some of these solutions like increased fuel economy. We're not in a crisis.

I think we have an enormous opportunity here today to really change that and look at the long term and really invest in technologies and the vehicles that will increase fuel economy and save us money driving our cars. I think it's been an enormous loss for the U.S. that we haven't taken the opportunity in so long to really increase the fuel economy of our vehicles.

And I'm definitely going to be in the market for a new car in the next several years. I hope I have the opportunity to spend some extra money that will also save me money in the long run, because I know that's an investment, that investing in those new technologies will also reduce costs for consumers, and they'll save money at the gas pump in the long run.

I hope that this hearing and this rule will contribute to ambitious new innovations that America can lead the way in putting cars on the street that are saving consumers money; and also helping solve global warming, bring down emissions. [Sic]

That brings me to the enormous cost of global warming that I want to address, to note that we need to make an impact to reduce our emissions in the next several years. It's apparent that we need to make enormous contributions to this with solutions that have economic benefits as well as environmental benefits. And this is the way to do it. I hope you will be very ambitious in this rulemaking.

And consider the effects on the near term, in terms of reducing U.S. emissions in the near term to consider how important it is to make early investments in technology, so that they are available sooner rather than later, you know, you need to get ahead of the game in solving global warming, as well as being a leader in international markets and in international debate on global warming.

In addition to that, in addressing the need to have economic and environmental solutions, we need to, you know, [sic] America is clamoring for solutions to high gas prices and to our oil dependence. And so I think it's necessary that we invest heavily in the solutions that, you know, benefit us, and also benefit our country, and help us continue to protect lands that are special and pristine.

I also just want to add that the figure you're considering right now for cost of gas is offensive to consumers. And I'm sure you know that, but we definitely need to be considering the higher cost of gas in our analysis. I paid $4.15 a gallon over the weekend driving around, and it's not easy. So please consider that in your rulemaking. Thank you.

MR. KRATZKE: Thank you, Ms. Forbes. We now have Deborah Linick speaking for Ron Halber.

MS. LINICK: Yes. Thank you very much. I'm Debbie Linick. I'm the assistant director of the Jewish Community Relations Council of Greater Washington. Our Jewish Community's national umbrella organizations, the Jewish Council of Public Affairs and the Coalition on the Environment and Jewish Life could not be here today, and so I'm delighted to testify here at their request.

The JCRC is the local chapter of JCPA, representing 210 Jewish synagogues and agencies in and around the nation's capital area. Clearly our Jewish community joins those of many faiths who urge careful stewardship of creation.

We believe that the best environmental initiatives must be economically just, not disproportionately burdening the poor. They must be sustainable over time, and grounded in sound science. The best policy should encourage participation by government, industry, institutions and individuals alike.

Urging strong CAFE standards meets each of these important goals. Increasing gas mileage of our vehicles is the best way to simultaneously save Americans billions of dollars in transportation costs, and cut down on the emissions that exacerbate global warming.

Furthermore, reducing dependence on oil, especially foreign oil, improves our economy and our national energy security interests.

For all of these reasons, we urge you to set strong standards, but achievable standards, and to do so in a transparent way that explains to the American people how stronger standards help protect the environment.

Americans are already paying more than $4 a gallon for gasoline in this country, all around this country. We must regulate fuel economy based on realistic assumptions about the likely future cost of fuel, and with an eye toward encouraging cleaner vehicles, and the pursuit of renewable and alternate sources of energy.

Thank you for inviting our testimony today. We look forward to strong standards deriving from an open and deliberative process. Thank you for allowing us to be part of that.

MR. KRATZKE: Thank you, Ms. Linick. I'd like to ask Rita Rodgers to speak, please.

MS. RODGERS: As I, let me introduce myself. I am Rita Rodgers, R-O-D-G-E-R-S. I was invited by the Union of Concerned Scientists. I do not represent them. I represent myself. I couldn't afford to join them.

As I talked with some of the younger people and listened to them, the first thing that came to mind was, when I drove an English Ford Angler with four cylinders I bought 25 cents worth of gas, and went 30 miles a gallon. That's a long time ago.

We are now at $4.15 a gallon. I think it spiked at $4 -- I don't remember, my 1993 Honda Civic EX gets about 35 to 40. My point is, I have a historical perspective here.

I recall that in the 1970's we had, "an energy crisis." We -- and the government responded, I thought, appropriately. They set standards. Nothing happened, because after that energy crisis passed, we didn't look down the road to see another energy crisis coming.

So here I go. Here's my background. I'd like to first thank the NHTSA for the privilege of speaking about our current energy crisis. My background as a scientist includes the following, a degree in experimental psychology, work equivalent to a BS in chemistry, and graduate work in both areas. University classes include years, two years of engineering calculus, physical and organic chemistry, ecology, et cetera, et cetera, et cetera.

As a scientist, I am not politically correct, which is why I'm unemployed now. I do not value the dollar over life on our planet. As every scientist knows, there is a reaction for every action.

For example, where does the energy go from underground nuclear tests? What effect have manmade disasters, and I have to add a little bit of politics in this, such as September 11, 2001, and wars had on our atmosphere in the form of particulate matter circulating the planet?

If we show the same disregard for clean air that we have shown for clean water resources, what happens to nature's capacity to recycle carbon monoxide. Carbon dioxide creates clean air. I suffer from asthma. And I can recommend as a chemist coffee. It's in the same family as Xanthese. It can give you a heart attack if you are not used to the drugs. Just an aside.

Deforestation and our prolific use of fossil fuels has had a disastrous affect on nature's ability to provide clean air. All this so those [sic] with enormous economic resources can drive the latest and largest SUV's and feel safer, from I don't know what, a terrorist attack.

From my knowledge of nuclear physics, and I didn't go into that field, believe me, I can tell you at ground zero and you're very lucky because you're vaporized. If a hardwood forest is clear cut and left to regrow, it takes 150 to 200 years for it to go through the successive stages to return to being a hardwood forest providing us with clean air. A hardwood forest is preferable to a soft wood or pine forest because the leaves of hardwood forest provide a larger surface area than pine needles for oxygen recycling.

It is my understanding that if we do not, if we continue business as usual, the planet might cease to exist within a century. That's not a joke. The way it would cease to exist, it would implode. It might implode from the destruction of the earth's crust.

For example, drilling. I give you the permafrost in Alaska as an example. Concrete, tar, nuclear tests. These are all assaults man has brought to the earth, to the planet. We don't have a lot of time here. It's time to get serious.

I hope Congress and the federal agencies responsible for the decisions about automotive efficiency will take [sic] these concerns into consideration for the sake of future generations. Thank you.

MR. KRATZKE: Thank you, Ms. Rodgers. Mr. James Keck, please.

DR. KECK: Good afternoon. My name is Dr. James Keck. I'm a preventive medicine resident at the Johns Hopkins Medical Center speaking today on behalf of the Environmental Defense Fund, or EDF, a national nonprofit organization dedicated to finding practical solutions to the most serious environmental problems.

EDF, while supporting the inclusion of climate change health impacts within the EIS is deeply concerned by the assertion that the agency and its consultants were unable to determine the magnitude of these impacts across the proposed CAFE alternatives, not only on the basis of climate change, but also regarding conventional pollutant health impacts.

We believe that NHTSA has failed to comply with the Ninth Circuit's previous mandate to quote, provide the necessary contextual information about the cumulative and incremental environmental impacts of the final rule in light of other CAFE rulemakings and other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes such other actions.

We are also concerned that even though EDFCA requires NHTSA to select the maximum technically feasible fuel economy that is economically practicable, the administration has deviated from this mandate and instead selected the standard that supposedly maximizes economic benefits. This so called optimized standard falls below alternative standards that convey less net economic benefits, but are still economically practicable and better meet the other recognized statutory considerations of energy conservation, environmental, and human health protection.

In its decision, the Ninth Circuit quotes from CJ Wall's dissenting opinion in City of Los Angeles versus NHTSA stating, we cannot afford to ignore even modest contributions to global warming. If global warming is the result of the cumulative contribution of myriad sources, anyone modest in itself, is there not a danger of losing the forest by closing our eyes to the felling of the individual trees?

And yet this is precisely what this EIS does. By presenting only the isolated impact of this one set of U.S. regulations upon the entirety of global climate change, and then asserting that health and other impacts are too uncertain to distinguish among the range of alternatives, NHTSA is certainly closing its eyes to the context of this regulation as well as the full set of cumulative impacts relevant to this EIS.

The EIS draws heavily upon the most recent IPCC report in describing the causes of climate change and its

tsh

impacts on the environment and human welfare. However, the EIS ignores the IPCC's description of targets for avoiding the most drastic of these impacts. For example, the IPCC states that avoiding a temperature increase of more than 2.6 degrees centigrade from pre-industrial times reduces the risk of key environmental and health vulnerabilities, and to do this, greenhouse gas emissions must peak within 10 years, and atmospheric carbon dioxide levels stabilize at less than 440 parts per million.

The absence of this critical context within the EIS leaves the public and policy makers unclear whether the preferred CAFE alternative will support a cumulative strategy to avoid the most serious climate change impacts.

Although the IPCC report provides a clear context and benchmark by which NHTSA can assess the alternatives, the EIS has failed to do so.

Let me next address the failure of the EIS to distinguish between CAFE alternatives and the basis of health impacts of conventional air pollutants. EDF and four other organizations called for a transparent quantification of health costs and scoping comments preceding this EIS.

The EIS notes that health costs are included within the Volpe model, used to select optimized alternative, but it fails to include estimates of adverse health events in its statement. And while the EIS provides the future relative reductions in tons of air pollutants across the different CAFE alternatives, it does not link these air pollutant reductions to health in a transparent and meaningful way.

To demonstrate that such a linkage is possible, we used a simple methodology to estimate the changes in meaningful health outcomes associated with a [sic] different CAFE alternatives.

Although I do not have the time to relay all of the specific details of our findings, the health protection resulting from, for example, the pollutant reductions in the cost equals benefits alternative versus the optimized CAFE alternative is measured in thousands of avoided deaths, and thousands of avoided asthma visits to the emergency department per year by the year 2020. We will include the full details of our analysis in our written comments.

In summary, this draft EIS fails in at least three key ways to fulfill its NEPA and EPCA mandates. First, the EIS does not provide an appropriate context to evaluate fuel efficiency in light of the IPCC consensus on the mitigation measures necessary to avoid serious climate, change health and environment impacts.

Second, NHTSA has not provided sufficient transparency to explain why it has departed from more stringent alternatives to better meet the energy conservation goal of EPCA.

And finally, the health impact assessment of conventional air pollutants lacks transparency and utility in that it does not provide meaningful information to policy makers and the public about the health benefits of more stringent CAFE standards. I thank you for your attention.

MR. KRATZKE: Thank you, Dr. Keck. Could I call Rabbi Fred Dobb, please.

MR. DOBB: Thank you. I'm Fred Scherlinder Dobb, a local public rabbi, and the Coalition on the Environment and Jewish Life is here. I'm on its board, as well as the Greater Washington Interfaith Power and Light, the Shalom Center, and Religious Witness for the Earth. And I'm here to urge you to prioritize the climate impacts of fuel standards, and to choose the path of conservation over convenience.

You must be overwhelmed by voices and perspectives today, along side your own proclivities. I hope and pray that you and all who make this decision are able to really maintain an open mind at heart, and be truly open to the evidence and ideas here.

That said, though I'm a man of the cloth, I'm not here to talk theology. I will cite ethical and moral standards. I happen to derive them from the biblical tradition, principals which compel our accuracy, our courage, and our alacrity in turning around this scourge of climate change.

Credentialed folks have already said what the American people get, [sic] anthropogenic climate change is real. Its early effects are seen now, worse lies ahead. A robust scientific consensus takes it very seriously. We bear disproportionate, historical, quantitative, and moral responsibility for it. And everything we do as individuals or national safety committees makes an incremental difference, a real one.

Fuel economy is a global concern, a concern of our nation. In my world it's a Jewish issue, too. Back in the Talmud, the law of not wasting, Baal Tasshchit, specified how you should properly burn the right kind of fuel of naphtha versus oil to get the right result. We had that consciousness 1700 years ago.

Our Jewish community today, through COJL offers a friend of the Court brief on California's clean air challenge to the EPA's non-waiver. We see urgency in curbing our oil addiction, our dependance, and in protecting all that we can.

And like many others here, I'm particularly concerned about calculations for the likely cost of gas in the future. Spiritually and ethically, we cannot reduce endangered species, flood and famine refugees, or the integrity of recreation to pennies in an equation, not that the draft EIS even accounts for them at all.

We cannot stand idly by while our country proposes to ignore the lion's share of logic and evidence, lowball the estimated price of gas a decade hence, lower fuel economy, and send aloft hundreds of millions of tons of carbon that could have been avoided.

It was Mark Twain or Benjamin Israeli who coined lies, damned lies, and statistics. Stats can be accurate. They need to be attempted. They can be harnessed for good, but sometimes they go the other way.

How we best guess the price of gas going forward, using current numbers, current numbers in Europe, which are twice our $4 a gallon, figuring futures markets, there are so many approaches we can take.

I'm no statistician, but as a citizen and clergy person it seems that whatever method yielded $2.25 or even $2.60 as an estimate for a decade out is an outlier at best, and a statistic beyond damn lies at worst.

This Yom Kippur I'll be speaking on responsibility to the other, the subtlety and impact of our personal choices. And I will address driving, the miles and hydrocarbons we take for granted.

I'll ask Adat Shalomers how to explain our profligacy in a conversation with a Bangladeshe or a New Orleanean, or other resident of low lying areas suffering ever more damaging impacts of rising sea level and stronger storms. And I ask you the same, as if not so much in hearing room as a confessional booth, a place of epiphany and reckoning, a day of atonement, when you will look back on your personal, like how and how much to drive, and your national choices, how efficient, ethical, and conservative to make our entire fleet. Looking back, did you do what was expedient or what was right?

Deuteronomy 30:19, I've set before you this day life and death, blessing and curse. You choose life, that you and your descendants may live. Our choices, with free will, have a real life and death implication for our great grandchildren. Please, let your and my great grandkids enjoy a slightly less denuded world. Please use reasonable numbers in your calculations.

As Rabbi Tarfone wrote 1900 years ago, it's not upon you to complete the task, but neither are you free to desist from it. A couple more mpg's won't solve climate change, but it's one of many manageable, meaningful steps that we all can and must take.

You're not supposed to solve this alone, but you must do your part as each of us must do ours. Please do yours with special emphasis on the least among us, the integrity of creation, and our descendants. Thank you.

MR. KRATZKE: Thank you, Rabbi Dobb. I'd like to call Fred Teal, Junior, please.

MR. TEAL: My name is Fred Teal, Junior, and I've come here today from Brookville, Maryland, just a bit north of the city, about 10 miles. I thank you for having me here.

Brookville is a very small town, and in that town I have my home with my wife and a 17 year old son. And I am here today because I'm very concerned about NHTSA's reluctance to upgrade corporate average fuel economy standards above minimum required levels.

I believe there is clear evidence that our air and our water temperatures are increasing steadily with serious consequences for our planet. Sea levels are rising, glaciers and polar ice caps are being reduced. Storms are gaining intensity. And rainfall is extreme in some places and nonexistent in others.

These changes are the result of the increasing levels of greenhouse gases that we now have in our atmosphere.

I understand that today's concentrations of CO_2 are higher than they've been in 600,000 years. Every extra gallon of fuel that we burn spews about 20 pounds of carbon dioxide into the atmosphere. We need to do everything possible to stop this.

My town recently decided to form an energy advisory committee and asked us to figure out what our carbon footprint was. We measured our electricity, our fuel oil, our propane, because we don't have natural gas, and other sources of emissions. And from that we learned that about 42 percent of our emissions came from our vehicles.

In my situation, I have a Prius and a Toyota Sienna. The Sienna is a 1998 model with 170,000 miles on it, and I'm kind of embarrassed to be driving it because it only gets 17 miles per gallon. For about the last four years I've been looking for a substitute.

I have three elderly parents and parents-in-law, and together there are six of us, with my wife and my son and myself. We need to take little trips together. I'm looking for something that's fuel efficient. I'd like to have something that would get 35 to 40 miles per gallon. You know there is no such vehicle on sale in this country today. There is no minivan that gets that kind of mileage. There are several SUV's that will seat five, but none that will seat six.

Do you know that since 2002 in Japan they've had the Toyota Estema, which is a small minivan that's a hybrid, and it gets about 45 miles per gallon. There is also a Mazda 5 which is sold here, but not with a diesel engine which gets around 40 miles per gallon with a diesel engine, but about 27 with a gasoline engine. But it's not being sold here.

It seems to me it's clear that the reason these vehicles are not being sold here that could meet my needs and help reduce global warming is because CAFE standards are not high enough to encourage vehicle manufacturers to bring these high mile per gallon vehicles in as part of their fleets. We need to make a change in that.

T. Boone Pickens, who is a long time republican supporter, and a very successful oil man is mounting a major effort to encourage us to switch to wind and solar and geothermal energy for power generation. He's also said, perhaps we could use a little natural gas to power our vehicles.

His main message is, "I've been an oil man all my life, but this is one emergency we can't drill our way out of." He's investing in a substantial amount of solar energy in a place called Pampa, Texas, in the middle of the state. This is going to create many new American jobs, with a great deal of new technology.

It should be very helpful if we begin to look at some of these technologies in terms of American jobs, and American development.

In summary, I wish to say that I disagree strongly with the arbitrarily low future gasoline prices contained in NHTSA's calculations. It's just incredible that you would use mileage figures for gas costs per gallon for gasoline that would be that low. It's just so impractical, considering our current situation.

I also disagree with your belief that we're not going to have any substantial amount of hybrid vehicles introduced until 2014. They've been around for years, and Ford and General Motors, Honda, Toyota, are making them and selling them today in large quantity.

I disagree with your assumption that the rate of adoption of hybrids is going to be as low as you say it is. I finally say, we stand at a fork in the road, and we can continue to consume fossil fuels and complain about high prices and make only incremental change [sic] in our energy policies, or, on the other hand, we can shift our sights to renewable energy sources and accept the investment and the other costs that that may entail.

I don't think it's a question of whether we're going to do this. Forces are going to push us into doing it because of the high cost of fuel, and because of the high demand coming from other countries. One thing is certain, the sooner we start our journey, the faster we'll reach our destination. Thank you.

MR. KRATZKE: Thank you, Mr. Teal. Is Alina Fortson here?

MS. FORTSON: Hi. My name is Alina Fortson, and I live and go to school in Berkeley, California. Thank you for the opportunity to comment today.

I am here because I think that addressing global climate change is one of the most important issues for this generation. I know that we currently have solutions that reduce greenhouse gas emissions in addition to improving our economy. If we don't act fast, we're going to lose the opportunity to make a difference.

Sutter Creek, the town where I went to high school, is in a rural area in Northern California. Public transportation is lacking, and many families live at least 30 minutes from basic necessities, such as supermarkets and schools, and close to two hours from Sacramento, the closest metropolitan city.

As you can truly imagine, the price and efficiency of fuel has a significant impact on this community. It is critical that we address both the economic and the environmental impact of our oil dependence, and take steps to curb them both.

In order to address climate change, scientists are stressing the importance of achieving an 80 percent reduction in greenhouse gas emissions by the year 2050. This means making small reductions in all of our emission areas, including transportation.

The United States transportation sector amounts to approximately 20 percent of our total greenhouse gas emissions. Therefore, measuring our progress requires considering reductions as a portion of that 20 percent, not as part of the global emissions. In this light, every small improvement does make a difference.

If we are to take advantage of our best, and most feasible technology, we would be in a position to reduce our oil use, in addition to lessening the impact that the price of gasoline has on families like mine.

NHTSA's current proposal hinders this potential. Your analysis uses assumptions for future gas prices that are simply unrealistic. Today, Americans are paying nearly $4 per gallon and there's currently no reason to expect prices to drop as low as $2.25.

Basing decisions on these faulty analyses is irresponsible and disregards NHTSA's duty to impose feasible fuel economy standards. I urge NHTSA to consider how this rulemaking increases the strain on the average family and to reevaluate your position on this issue and on climate change at large. Thank you.

MR. KRATZKE: Thank you, Ms. Fortson. Matt Kirby, please.

MR. KIRBY: Hello. I'm Matt Kirby. I want to thank you for this opportunity to have this hearing. I'm here for two reasons, and that's gas prices and global warming. And these are two crises that are currently facing our country. And they are two crises that NHTSA and the five of you sitting in front of me have the ability to severely help.

I'm from Wisconsin originally. It's a big state, it's a big agricultural base, and it's hurting. And both my parents, they aren't farmers, but they both commute two hours per day. They are strapped.

My dad teaches at a local community college. And several of his students have come forward with these really heartbreaking stories of how they have to cut food out of their food budget to pay to go to his class and to pay to go to work. And it shouldn't be happening in this country. It's criminal. And something has to be done about gas prices.

The only solution that's been presented so far is a stalemate in Congress because Republicans want to drill offshore which everyone knows, Bush' own administration has admitted, it's an insignificant drop in gas prices.

More importantly is facing the reality that this, the way our society is structured, this addiction to gasoline, which Bush has admitted, is fundamentally the cause of also global warming.

So we have two problems wrapped in one. And basically, there is one way to tackle both problems at once. Tackle the economic and the environmental, the gas prices and the global warming, and that's through fuel efficiency. And that's the power that you people hold in your hands and really need to grasp hold of.

The debate over climate change is done. We know this. I actually just finished a really great book a couple months ago that I was long overdue to read called, the End of Nature by Bill McKibben. It was the first major book written on global warming, and it was written in 1989, almost 20 years ago. And everything he says in that book has come to pass. The science was there 20 years ago, and no one has acted.

And in those, in the past two decades, the science has not only confirmed what he wrote, but actually the destruction is accelerating much quicker, much quicker than anyone actually imagined.

So now the science says we need 80 percent reductions by 2050, as several people have said. And one of the most significant being the cars and light trucks, the 20 percent, the 20 percent of emissions in this country, which emits 25 percent of global emissions. Twenty percent of 25 global emissions. That's the power you have. And that's what you can change and significantly alter the course of global warming.

As far as the environmental impact statement goes, we know we need to look at this proportionally to our domestic emissions, to our 20 percent of our domestic emissions, and not as part of the global outreach to get a better idea of how to evaluate it.

Also, NHTSA has picked 2100 as a time line for measuring success, which seems a little ridiculous, considering we have until 2050 to avert catastrophic climate change. So I would urge you to actually set a much closer goal, 2020-25 when you actually are going to begin measuring the success.

And it's setting the 35 miles per gallon by 2020, but actually to extrapolate this through 2100, to not say that 35 miles per gallon is the be all, end all fuel efficient standard, because it shouldn't be. That's an arbitrary number in and of itself, based on the unrealistic gas price of $2.25 assumption which is, frankly, an insult to my parents and an insult to the students who can't afford to eat.

Your own analysis shows that between 2011 and 2015 significantly higher standards can be achieved if you only up the presumed gas price at $3.14. So the use of these below cost energy estimates, it violates your own charter to impose mandatory maximum feasible fuel economy standards on a review of economic and technological feasibility. Thank you very much.

MR. KRATZKE: Thank you, Mr. Kirby. Jaafar Rizvi.

MR. RIZVI: Good afternoon. My name is Jaafar Rizvi. I'm a student. I grew up in Vermont. I go to school at Wesleyan University in Connecticut. I'm in D.C. this summer working.

I would like to thank you guys for having this hearing at a time where, you know, I've kind of lost a little faith in the government. It's nice to see the democratic process at work.

But I am here because I am concerned for several reasons that the fuel economy standards that you all have proposed are not strong enough.

According to the DEIS, fuel economy standards should be set at the maximum feasible average that the Secretary of Transportation decides the manufacturers can achieve in that model year, while simultaneously considering technological feasibility, economic practicability, the effect of other motor vehicle standards of the government on fuel economy, and the need for the U.S. to conserve energy.

And I agree with those guidelines. I think they're good. But I fear that NHTSA didn't properly analyze each of those specifically. For example, when considering economic practicability, the report doesn't really go into all of the economic benefits of lowering emissions, as well as the moral issues, which I won't talk about right now.

Emissions relate to global warming which cause or intensify natural disasters. And consider that $90 billion worth of damage was done by hurricane Katrina. That's $90 billion that can't be spent on something else. It can't be spent on helping our economy or investing in clean energy. Some would argue that those are the same things.

Now, of course, these disasters aren't entirely preventable, but it's within our power to lessen the severity of them.

The DEIS report states that 4 percent of the world's global warming emissions come from American transportation. And if we can lower these emissions by 25 percent, we're lowering the global emissions by 1 percent.

If a decrease in 1 percent could decrease, you know, the severity of the next Katrina by 1 percent, you're talking about saving thousands of lives, and you're talking about saving a billion dollars.

Moreover, we can expect to have more than one large disaster every year. We have been having tons all over the world. Katrina was the last huge one in the U.S. But the International Federation of the Red Cross showed in its 2007 world disaster report that there has been an increase in natural disasters of over 115 percent since 2004, totaling 541 individual disasters. It states that this increase has been due entirely to weather related disasters.

And this trend will continue unless a change is made, as there are more and more natural disasters, the amount of money and lives that are disappearing will only skyrocket.

For this reason [sic] I urge and I hope that NHTSA raises emission standards to a level that will consider long term economic and practical affects of global warming, and to reconsider in a more holistic view on economic practicability.

While the DEIS report shows very detailed calculations and extensive research, the claims of NHTSA just don't coincide with the claims of other incredibly credible scientific institutions. Like so many people have said, there's a call for 80 percent reductions by 2050, and this report doesn't seem to acknowledge that.

And that's fine, of course, but since, you know, research was done, but there's no description of where the divergence is coming from. And I've heard environmental scientists talk about why they disagree with this report. And I haven't heard any argument about why they are wrong. So basically, I'm left with the position where I feel like something isn't right with the research that's been done here.

And that makes me skeptical about analysis on two of the other categories that were mentioned before, the need for the U.S. to conserve energy and technological feasibility.

As it stands in the EIS report, optimal fuel economy standards will lower the increase in relative sea level rise from 37.9 inches to 37.8 inches. The decrease in the surface contour of the earth from .789 degrees to .788 by 2030, and that's just so minuscule.

I urge you to increase the standards to 35 miles per gallon by 2015. And I would urge you to consider that this won't cause undue stress on American car manufacturers. In fact, I have tremendous faith in the ingenuity and the ability of the American people, specifically those in Detroit, not only to successfully meet the high standard, but to prosper and thrive and become leaders.

So please give us the push that we all need, and in doing so America will become a leader in tackling the environmental crisis, one of the most important problems of our generation. Thank you.

MR. KRATZKE: Thank you, Mr. Rizvi. I'd like to call Ben Schreiber, please.

MR. SCHREIBER: Hi. Thank you for having this hearing, giving us a chance to talk about this important subject. My name is Ben Schreiber. I'm the energy advocate for Environment America.

Environment America is a federation of 26 state-based environmental organizations. It's also the new home for U.S. PIRG's environmental work, so we have split off and are our own organization now.

tsh

As the energy advocate here in Washington, D.C., I often get asked, what can we do about gasoline prices. And the solution that I'm coming up with, you know, the solution that I have in the short term is tire pressure and tune-ups. That's the best that I can come up with.

The truth is that after 30 years of failed energy policy, where we have the same CAFE standards that we did in 1975, all I can offer for consumers who are hurting right now is tune-ups and tire pressure.

We really need to do something about our fuel economy to offset the consumer's pain at the pump. And we're hearing a lot of talk about drilling. We're hearing a lot of talk about alternative energy. We're hearing a lot of talk about, you know, how what we need to do is increase supply. All of the talk that we're hearing about has incredible environmental impacts.

Increasing drilling off our coasts leaves us open to potentially having catastrophic oil spills, to infrastructure for drilling, to ruining our special and pristine wild places. And these are places that we need to protect. There's no reason that we should be drilling off of our coast, just because we can't get fuel economy right.

There's no reason that we should be subjecting the caribou and other endangered species in the Arctic National Wildlife Refuge to the riggers of oil production to the, you know, the roads and the drilling, and all of the other side effects that come along with it, just because we decide that we can't do fuel economy.

We've been saying since 2005 that we should be able to get to 40 miles per gallon with 10 years. The National Academy of Sciences said that we should be able to get to 37 miles per gallon within 10 years. And we just haven't acted. And this is without taking into consideration things like hybrid technologies, which are available today.

You know, we're using a price of gasoline of $2.30 to justify doing the bare minimum on fuel economy standards, and yet at the same time the price of $4 is being justified to open up our very last protected wild spaces to more and more oil and gas exploration. And it's unacceptable.

There are, you know, a couple of other serious concerns with the transportation sector and the fuel economy. You know, most Americans don't have choices about where to go when oil prices get high. They, we have very few public transportation options, and Americans are tied to their cars. So in the short term, there's very little that they can do to do that. [Sic]

So we are now feeling the effects of 30 years of inaction on CAFE. We don't want to be in that position, you know, 10-15 years from now. So we need to be taking the steps now so that we can be increasing fuel economy so that we can set the framework so that 10 or 15 years from now when these standards actually kick in and we're getting the new vehicles into the fleet, we're seeing reductions in fuel economy -- I'm sorry, in prices so that Americans can save money at the pump, and so we don't have to drill in our last wild protected spaces, and so we don't have to be dependent on foreign nations for our oil and energy needs. So thank you very much.

MR. KRATZKE: Thank you, Mr. Schreiber. Is Sarah Alderfer here? No. All right. Thank you for this panel. At this point we are going to call the last listed group that we have.

I'd like to invite Ami Greener, Robert Dawes, Catherine Easton, Elizabeth McGurk, Lala Shamerzan, Natia Hess, Brian Fleming, Sean Calvo, Chad Dougherty, Marsha Rucker, and Charles Yoder up to the table, please. Well, Ami Greener is first.

MS. GREENER: Thank you for the opportunity to speak before you. My name is Ami Greener, and I'm the energy policy specialist and legislative assistant for the American Jewish Committee, which I'm representing here today.

We're the nation's oldest human relations organization with over 175,000 members and supporters represented by 31 regional chapters in the U.S. and eight overseas.

AJC is a long time advocate of the need to develop energy policy that will reduce our nation's dependence on foreign energy sources as well as protect the environment. More than 30 years ago, prompted by the then recent Arab oil embargo, AJC first adopted a policy statement on energy.

Over the succeeding years, as the nation coped with energy supply shock in the seventies, coupled with concerns about the environment, safety and tanker dependency, agency adopted and acted on several additional statements that reflected the agency's concern that our nation address an increasing dependence on imported oil, and its impact in a fashion consistent with protection of the environment, and attention to policy impacts on the disadvantaged.

The 911 attacks underscored another crucial consideration, that our national security and our position as world leader are seriously undermined by our dependence on foreign nations.

All too often dollars used to purchase important oil end up supporting regimes such as the governments of Iran and Venezuela whose values run counter to those of America, and in some instances present a strategic threat with potential to disrupt oil supplies world wide, adversely affecting the world and U.S. economies with resulting loss of jobs, a decreased quality of living, and harsher conditions for low income families.

Further, the great transfer of wealth abroad created by our reliance on foreign oil sources, whether to hostile regimes or otherwise, diverse resources that if invested at home could help create good jobs and fund much needed investments in education, social initiatives, and physical infrastructure.

As we've experienced in the past, energy prices have decreased for periods of time, and with such fluctuations, Americans have become less sensitive to the need for this type of policy. Today, they've seen record prices at the pump.

We feel that the need for further action on energy security is more urgent than ever, both by assuring safe and sustainable energy sources, and through renewed attention to issues of conservation and efficiency.

While the U.S. comprises less than 5 percent of the world's population, it consumes approximately 25 percent of the world's oil. Two-thirds of all oil consumed nationwide in the U.S. goes for transportation. A drop in domestic oil production, coupled with increased consumption, has created a scenario by which the U.S. is more reliant on foreign oil sources than ever before.

Moreover, climate change, which the weight of scientific opinion holds is accelerated by greenhouse gas emissions from the use of fossil fuel, has the potential to disrupt our way of life, permanently damage the natural environment, create humanitarian crises, and provoke political and strategic conflicts worldwide.

Investment in a clean, renewable energy grid would both reduce greenhouse gas emissions and restore America's technological leadership, helping to build a sustainable economy to again create jobs and wealth at home.

The weight of the evidence demands that we devise policies directed at stemming climate change, was well as adapting to reality. In urging these policies we act in accordance with the Jewish tradition which commits us to the protection of life, stewardship of the earth and its inhabitants and the well being of future generations.

Last year a historic step was taken when President Bush signed into law the Energy Independence and Security Act that included among other provisions a strengthening of CAFE standards for the first time in more than two decades. We think the strengthening of the CAFE standards is one of the most crucial components of a multi-faceted approach to drastically reduce our dependence on foreign oil, reduce global warming emissions, save money at the gas pump, and help secure America's energy future.

These standards, for example, would save the U.S. 1.1 million barrels of oil per day by 2020, approximately 40 percent of what we import today from the Gulf, the Persian

Gulf, I mean.

In proposing a combined average of 31.6 miles per gallon for model year 2015, NHTSA is failing to acknowledge the current technology that could safely and cost effectively make all vehicles reach state-wide fuel economy average of at least 35 miles per gallon by that year.

Further, the current proposal relies on fanciful gas price assumptions, which result in insufficient fuel economy levels. The proposal assumes future gasoline prices of $2.25 per gallon, when American consumers are already paying prices nearly double that today.

The use of the low cost energy estimates violates the agency's charter to impose mandatory maximum feasible standards based upon a review of economic and technological feasibility. NHTSA must reconsider the proposed standards and use its authority to meet the urgent need of the U.S. to conserve oil and meet the growing demand of American consumers for vehicles that go farther on a gallon of gas.

NHTSA should not conclude in its analyses that fuel economy gains are presumed to stop at 2020 levels, but further grow by means of using existing technologies. We see the use of alternative and renewable fuels, new lightweight materials, and electric vehicles taking up a bigger percentage of miles driven in the U.S. in the near future.

Last statement. We cannot overestimate the importance of moving towards tougher fuel economy standards this time. Even if we -- we shouldn't underestimate the challenges this and other actions addressing energy security will entail. But we see no alternative if we are to put the United States in a more sustainable energy path, essential to both our nation's security and environmental health. Thank you.

MR. KRATZKE: Thank you, Mr. Greener. Is Robert Dawes here?

MR. DAWES: Good afternoon. My name is Robert John Dawes, and I am from (indiscernible) County, Pennsylvania. First and foremost, I greatly appreciate the opportunity to testify before NHTSA today. I come from and represent a small rural farming community located about three miles from Lancaster County, one of the most productive non-irrigated areas of farmland in our nation.

These farmers, who primarily run small dairy and beef operations are the epitome of hard working Americans, are the model for what this country was founded on. Unfortunately, they are now victims of global warming, as well as record high gas prices.

For the past four summers, Pennsylvania has undergone the worst droughts in decades, thus making it virtually impossible for farmers to grow corn, and various feed stocks for their animals. Global warming, coupled with outrageously high fuel prices, has forced many honest, hard working Pennsylvania farms from their homes.

I speak from personal experience, because on my Angus beef farm, the corn crop which we have used to feed our herd or years has required us to consider the use of irrigation for the first time due to low crop yield. Furthermore, the amount of money spent on diesel fuel for one truck as well as one tractor has matched some farmers yearly revenue.

It is gut wrenching to watch my neighbors and fellow farmers sell homesteads that have been in the family for years because of global warming, as well as high gas prices.

Despite these bleak circumstances, I remain hopeful and optimistic. I am optimistic that with the help of NHTSA we can start making manageable emission reductions. For each carbon emitting sector of our economy, each reduction will be part of a larger long term emission reduction plan. As much as I would like there to be a band aid or a short term fix for the farmers of Pennsylvania, there isn't, and all of my peers involved in agriculture know and accept this.

With the increase of global warming emissions and growing oil dependence, our country, not just Pennsylvania farmers, are put at risk. Americans are spending billions of dollars at the fuel pump and yet impacts of global warming are still affecting our nation at an exponential rate.

I hope that NHTSA understands the dire necessity of putting existing fuel saving technology to work by increasing achievable standards for vehicles produced in future years. By doing this alone, these standards would save $54 billion dollars of gasoline over the five years addressed in rulemaking.

Furthermore, by setting standards to 35 miles per gallon in 2015, an additional $22 billion dollars in gasoline would be saved. This translates to 280 million metric tons of CO_2 out of the atmosphere.

Pennsylvania farmers are one part of America that is being hit the hardest by the impacts of high fuel prices and global warming. I'm confident that NHTSA will do everything in their power to stop this quintessential part of American identity from being lost. Global warming is a long term problem in need of immediate action and cooperative long term solutions, thus ensuring a secure energy future for all Americans, as well as the farmers of Pennsylvania. Thank you.

MR. KRATZKE: Thank you, Mr. Dawes. Is Catherine Easton here?

MS. EASTON: Hello. My name is Catherine Easton. And I'm very thankful for this opportunity to testify today. I feel very strongly about this issue, both as a citizen concerned about global warming, and as a consumer dealing with high gas prices.

Global warming is happening right now, and reducing greenhouse gas emissions by 80 percent by 2050 will save us from the worst effects of global warming. But unfortunately, as I think we've all noticed, 80 percent is a lot and increasing CAFE standards will not achieve this.

In fact, no individual sector could reach such a dramatic decrease. And this is why we must strive for smaller achievable decreases in all sectors. These small decreases combined could make a substantial difference.

There is no point doing nothing, giving up, and ruining the planet for future generations, for my generation and my generation's children, simply because increasing CAFE standards alone won't make the required difference.

So this is a simple step, and let us prove that the United States does have the technology to do this. Let us set a good example for other nations. We worry about China and India developing, and the added pollution that will cause. Let us pave the way towards a solution.

Fuel economy standards are already higher in Europe than in the U.S., so the technology is available to the auto industry, but the industry feels threatened by the changing of the status quo, and opposes these higher fuel economy standards, just like the industry opposed seat belts, and just like the industry opposed air bags.

But seat belts and air bags did not hurt the auto industry, and neither will increased CAFE standards. In fact, with the price of gas over $4 a gallon, consumers are looking for fuel efficient vehicles.

If saving the environment isn't an important enough reason, if having a safe nonhazardous planet for future generations to live on isn't enough motivation, then increase CAFE standards to save our wallets.

Higher gas prices increase the price of going to work, so people need to pay exorbitant amounts of money just to make money. Senator McCulsky from Maryland said that when President Bush took office, the average family spent a little over $3,000 a year on gas. Now that average family spends $5,000 a year on gas, and pays more for food, too, because of higher transportation costs.

$2,000 sends a kid to a community college for a year, and $2,000 can alter a family's lifestyle. We pay too much for gas, but more drilling is not the solution. People have been warning for years that there is a finite supply of oil.

Even if we grant oil companies new leases for drilling, it will be 10 years before oil from those leases will be pumped into our cars. Even if we drill more, we will still not produce enough to satisfy U.S. demand. We will still depend on foreign nations for oil, and we will still risk our national security for oil.

Even if we drill more now, there will still come a time then the world's supply of oil runs out. We must fight our addiction to oil, reduce our oil consumption, so that when that day comes, the United States economy will not crash.

Agriculture, industry, transportation and services will continue by using alternative energy sources. This is not a transition that can happen overnight. We cannot wait for the world to run out of oil to begin looking for alternatives. This must be a gradual transition. So why not start by improving CAFE standards. Thank you.

MR. KRATZKE: Thank you, Ms. Easton. Elizabeth McGurk.

MS. McGURK: Hello, and thank you for this opportunity. My name is Elizabeth McGurk, and I am here because as a person of faith, an employee of the National Counsel of Churches and Christ, I recognize that we all have a responsibility to be stewards of God's world, and to care for one another.

Achieving higher fuel economy standards for U.S. cars and trucks is one of the most important actions we can take to reduce our greenhouse gas emissions which are causing global warming and impacting both God's people and God's planet.

Increasing CAFE standards is a critical step that must be taken to reduce pollution and curb greenhouse gas emissions that cause global warming, while protecting those who already suffer from high gas prices.

Improved CAFE standards would mean more vital discretionary income for low income working families to spend on necessities like food, health care, and housing. Significantly improving CAFE standards will also reduce U.S. dependence on oil, and decrease the need to open sensitive wilderness areas, including the outer continental shelf to oil and gas exploration.

As a native Floridian, I know too well that our communities are already beginning to feel the effects of global climate change. During my freshman year at Eckert College in St. Petersburg, Florida, in 2004, we were evacuated four times in one month for four different hurricanes.

I am worried about the ways in which global climate change and our country's dependence on extractive nonrenewable resources will affect my home state, and my friends and family members living there. I know that the costs, both tangible and intangible of doing nothing will far exceed the cost of taking action now.

I urge you to strengthen the current proposed standards by setting a new standard of at least 35 miles per gallon by 2015.

Genesis 2:15 calls us to till and tend the garden. Toward that end, we have a moral obligation to choose the safest, cleanest, and most sustainable sources of energy to protect and preserve God's creation. God calls on us to be wise caretakers of the earth's gifts, protecting air and water quality, as well as ecosystems and human community. Good stewardship includes reducing to the greatest extent possible the human generated carbon dioxide emissions that are causing global warming. Thank you.

MR. KRATZKE: Thank you, Ms. McGurk. I can run down this list of names, but I think you're Ms. Spear, and before you go, sir, would you like to -- yes. I think you're the last one. Or I can read off Layla Shamarisian, Mataya Sess, Brian Fleming, Sean Calvo, Chad Dougherty, Marsha Rucker, Charles Yoder. Very good. Mr. Yoder.

MR. YODER: My name is Charles Yoder. I'm from Baltimore. For identification purposes, I retired about two and a half years ago from a 35-year federal career that included 12 years on the staff of the Senate Committee on Veterans Affairs, and most recently four years as counselor to the Secretary of Veterans Affairs.

Now, I hasten to add that I am speaking for myself and not any government department or member of Congress. I have been retired for over two years.

And I think we can stipulate the importance of climate change. CAFE standards are one step that the Congress has taken to address that challenge. And I think we can say, and I want to emphasize that climate change is not abstract. It's real. The words that you write are not an abstract environmental analysis. They're not a sterile exercise in rulemaking. They'll affect the planet. They'll affect everybody that lives on this planet.

But your charge right now is an EIS. I've noticed that your EIS puts your actions, proposed actions and alternatives in the context of the world. That was addressed by someone as I came into the hall earlier, in the context of the entire planet, not just in terms of the U.S.

If you choose to do that, then I think we need to look at the implications of our national addiction to oil in a world context, in a world wide context.

Our country invests enormous treasure and enormous numbers of lives ensuring our access to oil. In my career I veterans affairs I've talked with surviving spouses, with orphans of young men and women who have died protecting our access to oil. I've talked with young men and women who were maimed for life protecting our access to oil, and it is those conversations that drag me down here from Baltimore.

Now, you will correctly note that you are writing an environmental impact statement, not a human impact statement, and this is not the forum to discuss whether or not that's an artificial discussion. But if the U.S. is going to continue our addiction to oil, then we need to address the impacts on a worldwide basis, and the environmental costs of any standard other than the strictest possible standard are enormous simply because there are powerful nations, not just the U.S., there are many powerful nations seeking access to a limited supply of a resource that overwhelmingly is located in an unstable part of the world.

And I think it's only reasonable to assume that there will be additional conflicts over the next generation, and that those conflicts will have enormous environmental impacts.

So if you're going to consider things in a world context, you need to consider the environmental impact of future wars, and those impacts must weight on the balance as you make your decision of the alternatives available to you in this rulemaking process. Thank you.

MR. KRATZKE: Thank you, Mr. Yoder. Ms. Spear.

MS. SPEAR: Hello. My name is Emily Spear, and I thank you for allowing me to speak today. I am here to voice my concern about the imminent impacts of global warming and the effects of our strong dependence on oil.

Growing up in Southwest Florida, I spent much time exploring beaches, fishing, and learning about coastal marine and wildlife. I love going to Sandibel Island and Captiva to enjoy the outdoors, bike riding, picnicking, walking around town.

Unfortunately, these beach communities and islands are now threatened by global warming. I'm concerned that my grandchildren may not have the same opportunity to enjoy this area and to see the same beauties which I have been so lucky to see.

At the rate we're going, pieces of Sandibel and Captiva may be gone before my grandchildren or my great grandchildren are old enough to visit these treasures, or smaller Southwest Florida barrier islands in their entirety may be lost forever.

Increasing fuel economy standards would be one step in curbing global warming. Scientific reports have concluded that in order to avoid catastrophic effects of global warming, we must reduce our greenhouse gas emissions by 80 percent by 2050, 2050.

This issue is staring us in the face, but I believe that NHTSA can do its part by requiring vehicles to be more fuel efficient. We know that carbon emissions from transportation mechanisms are great at 20 percent, which contribute directly to global warming. However, it concerns me when NHTSA's draft environmental impact statement analyzed the resulting benefits of greenhouse gas emissions from higher fuel economy standards in an improper context, which makes the greenhouse savings appear insignificant, though increasing fuel economy standards to 35 miles per gallon by 2015 would save 280 million metric tons of carbon dioxide.

The transportation sector has the power to help decrease the amount of carbon emitted into the environment by increasing the fuel efficiency standard.

My second main concern is about America's dependence on oil, as it is a national security issue. Our country feeds off of foreign oil, which causes us to be in the pockets of many nondemocratic governments. Increasing our fuel economy standard to 35 miles per gallon by 2015 would save us 300,000 gallons of oil per day by 2020.

Taking this simple and achievable action would help us decrease our dependence on oil, would allow us to take back control, and would help stabilize some issues with security.

Increasing the fuel economy standard would be one step, one great step toward the path that many other sectors could also, and should also follow. This is a community effort. We can do this. The transportation sector has the ability to add their contribution by increasing fuel economy standards, if we know that currently America has the capacity to increase standards to 35 miles per gallon by 2015, what's stopping us?

We have the ability to lead the world by setting an example. We have the ability to make our country more independent. We have the ability to save future generations. We need to make the choice to increase fuel economy standards. Thank you.

MR. KRATZKE: Thank you, Ms. Spear. At this point, we have run through the list of speakers who were registered. Is there anyone here who would like to speak who hasn't already done so?

If not, I would like to sincerely thank each of you for your comments on the analysis and our Draft Environmental Impact Statement. I am sure that I'm speaking for the entire panel when I say that it's different and it's more immediate when you hear and see a person, as opposed to just reading their thoughts.

You've given us a lot to think about. We want you to know that your views, your thoughts are very important to NHTSA on this subject. Please make sure that you submit comments to our docket. It's open. It closes in two weeks.

If you could give us something in writing in addition to this, we have taken a transcript. It will be in the docket. So we will consider this. But if you have other things you've thought of or smaller points that didn't fit into five minutes, it would really be helpful to us if you would submit that to our docket which closes on August 18th.

Thank you for taking the time to come here, and that's it for us today. Thanks again.

(Whereupon, at 2:51 p.m., the hearing was concluded.)

C E R T I F I C A T E

Amery, WI, 54001

I find it truly amazing that in the past when environmental rules were promulgated EPA justifies them with health risks and estimates of deaths. In the case of fuel economy you are disregarding this very concern. To achieve high fuel economy standards vehicles will be made of lighter less strong materials which will make the vehicles less safe and significantly increase highway fatalities. I find it disingenuous that in this case human health can be discounted. This rule is being promulgated to address climate change. Over 32,000 scientists have signed the "Oregon petition" stating they see no convincing scientific evidence that humans are causing catastrophic climate change. They have been joined by the American Physical Society, which recently announced that it was reassessing its prior position - that evidence for global warming was "incontrovertible" - because mony of its 50,000 physicist members disagree strongly with climate chaos claims. Rules should be promulgated based on reality and science not politics especially in this case because people will die.

I know we have had for years the technology to run more efficient vehicles on alternative fuels. I know that the greed of Big Oil has been suppressing this knowledge. It is time to get realistic and start operating out of concern for our environment rather than caving into the pressure of unscrupulous industry.

Dear NHSTA:

Even the President now recognizes the reality of anthropogenic global warming. This threat to the biosphere combined with increasing acidity of the earth's oceans caused by increasing atmospheric CO2 necessitates the need for early implementation of rigorous fuel economy standards independent of "paying-for-itself" considerations. America's auto industry needs to have its feet held to the fire and quickly. If Japanese manufacturers can do it, why can't "Detroit"?

Thank you for your action. Robert Burchard, Ph.D.

I am severely disappointed in the national response to both reducing our desperate need for foreign oil and addressing the myriad environmental damages that heat-trapping gases are causing.

I think it is hugely embarrassing that the United States of America has failed to adopt much higher fuel efficiency standards for all vehicles here. As a hybrid driver, I know that my own vehicle regularly achieves 47-52 mpg in normal driving conditions in town and on the highway, so I am disgusted and saddened by our once- innovative, once-strong American car companies "reaching" for marginal improvements in fuel economy. American government has enabled the current state of affairs.

Please do the right thing by our great nation and mother earth now-- insist on MUCH higher-- already implementable -- standards that dramatically increase fuel efficiency of U.S. vehicles in the near term.

Thank you for your consideration of my comments.

Dear Congressmen--

How can you expect to lead the change needed for a sensible energy policy when you disguise the math? Methinks your math teachers in high school would keep you after school.

As of today the average price per gallon of gas is 4.07 -- not 2.25 or 2.60 a gallon. That was what maybe 2006? So auto manufacturers don't feel the need to change fuel efficiency standards when these sorts of numbers are given as what is paid at the pump by Joe Bagadonutz of Anywhere USA.

You need to wake up and get real. Maybe listen to an oil man like T Boone Pickens if that helps. We are not going to drill ourselves out of this problem esp since we keep on allowing drunks and uncertified drivers to dump oil into our sacred waterways.

Wake up!

James Farrelly

I BELIEVE THAT ALL EFFORTS SHOULD BE MADE TO PRODUCE AN AMERICAN CAR AND IMPORTED CAR WITH THE HIGHEST MPG POSSIBLE, I DON'T MEAN 25, I MEAN WHAT THE PRIUS IS TOUTING 45MPG.

IT IS ALSO POSSIBLE TO INCLUDE TECHNOLOGIES WHICH CAN INCREASE THIS FURTHER. I ALSO BELIEVE THAT SOMETHING SHOULD BE DONE TO PROVIDE ENERGY EFFICIENT MASS TRANSPORTATION TO REDUCE THE WASTE THAT HAPPENS WHEN TRAFFIC BACKS UP AT RUSH HOUR WITH PEOPLE IDLING AT 0 TO 10 MILES PER HOUR FOR THE 3 HOURS OF RUCH HOUR WHICH HAPPEN IN THE MORNING AND THE EVENING. I ALSO THINK THAT BUSINESSES AND GOVERNMENT BE GIVEN THE INCENTIVES TO PROVIDE WORK FACILITIES IN THE SATELLITE SUBURBS WHICH EMPTY AT 4:00 AM EVERY DAY. MAYBE A SCHEULING OF WORK TIMES FOR LARGE COMPANIES WHO EMPTY A RUSH HOUR, MAYBE THIS COULD BE STAGGERED. ALL THIS WOULD TAKE A STRAIN OFF THE INFRASTRUCTURE WHICH CAN NOT BE REBUILT EVERY TEN YEARS TO ACCOMODATE THE GLUT.

There are strong enough reasons to switch from a gasoline-fuel based economy to a more progressive, cleaner alternative.

1) Crude oil is dirty. Even if one is debating that greenhouse emissions have no effect on our weather patterns, it is still dirty. It can bring life to a machine but it destroys so many other things (animals caught in oil slicks, the process of extraction from the earth, smoke going into our lungs...)

2) Dependency on oil is bringing too much greedy politics into our lives. These oil companies have too much influence on our banks and policies. They are only concerned with their profits and will push us to the brink financially to get more money and power for themselves. The domino effect of greed is misery that only darken our human existence.

3) Foreign oil keeps locked into a bloody war that taints our humanity. It is time to stop doing business with those who have been rivaling for thousands of years, let them figure out their own affairs, and let us focus on taking care of ourselves first. And that means switching to a new system of fuel. NOW.

4) We are able now more than ever to change our relationship to life; Proactively reaching for technologies that benefit everybody and living as a unified community all sharing this planet. We do so because we are evolving by choice. Darwin observed that the species who thrives the most is the one who thinks of the survival of the whole. It is a point that has been ignored for rugged individualism, an error which needs to be corrected.

If history repeats itself, then it's time to re-write our story and begin the creative journey toward new technologies worthy of our hopeful future.

Thank you,

Melissa Briese

Greetings:
I write since I cannot attend your public hearing on fuel economy standards on Aug.4.

The need for an aggressive reduction in fuel usage is not only about an attempt to keep the cost down -- it's about the need to drastically conserve what remains for future generations. Please get with it.

Sincerely
John R. Schieber

While I will not be available for the DC meeting, I do wish to state my disgust with the current state of petroleum pricing and economy factors.

I have already discontinued use of motor vehicles due to the excesses in gasoline price gouging, automobile misregulation and resultant overpricing, and the state of insurance scams. I use a bicycle, which only uses minuscule amounts of lubricant and occasional tyres and innertubes vice guzzling drastically overpriced fuel. I do not value a gallon of gasoline over 75¢, a 200 liter barrel of oil over $15, nor place any value on the current 'standard features' forced into cars that have driven the new vehicle prices way over reasonable levels.

We had it once, back near the middle of last century. The Fish carburetter, the Baker Electric Car Company, the Moller Company, and others are signs of the stolen promises of a future lost to political scams, greed, and fraud. We should have had a working toroidal or impulse fusion reactor design already, not be penny-pinching research while our supposed leaders skim off the funds.

Honest pols may be able to cushion the fall of this part of the nation, though I doubt even that would save it. The petrochemical scam has already lost me. I can only hope that the current failures don't explode on impact...

Dear Sir,

The U.S. public understands that strong fuel economy standards are a primary path toward addressing high energy prices and global warming pollution from autos. An excess profit tax is mandatory, if this objective is to be achieved and raise the funds necessary to support the research necessary to become free from fossil fuels for the world's increasing energy needs.

Not only do we have to find alternative fuels to regain our independence from other countries. We also must increase fuel economy/energy efficiency, to better stimulate our economy, and reduce our carbon footprint. We have taken small steps towards solutions, when we should be taking broad leaps, and bounds. Our future depends on energy alternatives, and we should not depend on petroleum to guide us through life. If we don't start acting on behalf of the greater good of America, and on behalf of the American people, we will create a self-inflicting decline in our National security, and not only become more dependent on other countries, but we will be owned by them.

Our time is now!

In Liberty,

Your friend in peace,

Mike Wadas

Sirs,
I support REAL WORLD fuel economy standards, and whole heartily support increasing these standards toward the goal of 100mpg. The cost of fuel is driving our economy into a depression and will soon bankrupt our country.
For to long the government supported an easy way out for the auto manufactures. It is time for real progress.

We need to raise cafe standards not erode them. It is insane to drill in environmentally sensitive areas when we can directly reduce demand for oil by mandating that all passenger cars get at least 40 mpg by
2012. It is so clear, double the mpg and you double the fuel supply.
Our cars are vastly overpowered and we can and should put smaller engines into our cars and then work to make them more aerodynamic.
Too many American cars use plastic bling grills for looks that create terrible aerodynamics. Instead, we should use that plastic to make cars lighter and more fuel efficient.

I am writing to protest the ridiculous assertion that we will be paying between $2.25 to $2.60 per gallon for gas through 2020. DOT is calling for fuel economy improvements only if they pay for themselves through fuel savings—the money saved from the gas the cars wouldn't use.
This gas price fantasy allows automakers to shave three to four miles per gallon off of the historic new fuel economy requirements that became law in 2007. If accurate gas prices are used, the new requirements would further reduce global warming pollution equivalent to taking about 10 million cars off the road.

Obviously, strong fuel economy standards are a primary path toward addressing high energy prices and global warming pollution from autos. I must express my outrage over this gas price ruse!

Cleaner cars are an absolute necessity in the effort to ameliorate the effects and perils of rampant global warming.

Sincerely,
Nancy Miller, RN

--

Sarah E Larsen
FL, 33928

My name is Sarah Larsen and I am an Environmental Engineering student at Florida Gulf Coast University in Fort Myers, Florida. As a Florida resident, I am incredibly concerned about the impacts of global warming on my state. I am here because I think NHTSA has a responsibility to put into place the strongest fuel efficiency standards possible to help reduce our global warming emissions from vehicles.

Global warming presents Florida with serious challenges that threaten human health, economic prosperity, and treasured natural areas. Over several decades, changes in sea level, average temperature, and weather will affect coastal property and beaches, water resources, agriculture, and ecosystems. Global warming has the potential to affect everything that defines Florida.

Scientists have already observed changes in Florida that are consistent with the effects of global warming. These changes include retreating and eroding shorelines, dying coral reefs, salt water intrusion into the freshwater aquifer, increasing numbers of forest fires, and warmer air and sea surface temperatures. In coming years, these effects may become more common, and increasingly severe.

Florida’s land, water and reefs support thousands of animals and plants, including five species of sea turtles, and nearly 120 endangered, threatened or species of special concern such as the American crocodile, wood stork and West Indian manatee. The state also is home to the world’s third largest coral barrier reef. It shelters more than 18 million full-time residents, and attracts millions of seasonal visitors annually. With nearly 1,200 miles of coastline and 95 percent of its population living within 35 miles of the coast, Florida is uniquely vulnerable to climate change. It is not just the environment that will be affected. Three key economic sectors in Florida are directly tied to the health, productivity and beauty of the natural world’s agriculture, tourism and fishing. Florida’s economy, as well as its communities and native habitats, will likely sustain heavy damage as the planet’s temperatures and oceans rise in response to human-induced global climate change.

Florida needs NHTSA to put in place the strongest fuel efficiency standards possible to help reduce our global warming emissions from vehicles.

I feel the most disappointing thing about the Draft Environmental Impact Statement is that it fails to analyze the benefits of greenhouse gas emission reductions in the proper context. When NHTSA tries to determine the difference in global ocean temperature rise in the year 2100 resulting from a 31.6 mpg standard vs. a 35 mpg standard, statistically, there is none; however, this does not mean that raising fuel economy standards faster will not have a significant impact in our struggle to reduce global warming pollution.

In the United States, emissions from the transportation sector account for roughly 20% of our country’s greenhouse gas pollution; therefore, any projected decreases in greenhouse gas emissions arising from increased fuel economy standards can never be greater than 20%. For that reason, reductions should be considered as a proportion of the 20% - not as a proportion of the entire planet's combined carbon emissions.

In addition, NHTSA takes a presumed 35-mpg fleet in 2020, assumes that fuel economy stops increasing, and then measures the cumulative CO2 savings through the year 2100. I believe NHTSA should only be measuring reductions at the 35-mpg fleet level for the life of these vehicles. Fuel economy should not be presumed to stop at 2020 levels. If NHTSA wants to evaluate carbon savings through the year 2100, then they should do so by assuming fuel economy standards continue to increase to the year 2100 at the same rate of increase as between 2011-2015. Furthermore, considering that relevant science is talking about reductions needed by 2050, it again seems out of context for NHTSA to have randomly picked the year 2100 as timeline for measuring success of today's carbon reductions from vehicles. I believe success and progress should be measured by how close these fuel economy improvements get us to reducing the transportation sector's carbon emissions by 80% in time for the 2050 deadline. To do otherwise fails to realistically evaluate vehicle emission reductions as a key part of the strategy to curb global climate change.

Although there is no magic antidote to get us to an 80% reduction in CO2 emissions by 2050, one of the single biggest step we can take in this country to reduce our global warming emissions is to make our cars and trucks go further on a gallon of gasoline. The technology exists today to safely and cost-effectively make all passenger cars and light trucks reach a fleet wide fuel economy average of at least 35 miles per gallon by 2015. Taking this step will achieve the goals of the new fuel economy law and as is most pertinent to this hearing will greatly reduce the global warming emissions from the transportation sector.

NHTSA has proposed standards for both cars and light trucks in response to the Energy Independence and Security Act's mandate to achieve a fleet wide fuel economy average of at least 35 mpg by 2020. NHTSA proposes to raise the fuel economy of cars and light trucks to a combined average of 31.6 mpg for Model Year 2015. While this increase is more than half of what is required to meet the mandate of 35 mpg by 2020, I believe NHTSA fails to take full advantage of available fuel saving technologies, and fails to fully and fairly evaluate the benefits of greenhouse gas emission reductions.

As a college student and Florida resident, I urge NHTSA to reconsider the proposed standards and use its statutory authority to mandate a fleet wide fuel economy average of 35 mpg by 2015.

Berkeley, CA,

General Comment

My name is Alina Fortson and I live in Berkeley, CA. Thank you for the opportunity to comment today.

I am here because I think that addressing global climate change is one of the most important issues for this generation. I know that we currently have solutions that reduce greenhouse gas emissions in addition to improving our economy. If we don?????????t act fast we are going to lose the opportunity to make a difference.

Sutter Creek, the town where I went to high school, is in a rural area of northern California. Public transportation is lacking and many families live at least 30 minutes from basic necessities such as supermarkets and schools and close to two hours from Sacramento?????????the closest metropolitan city. As you can imagine, the price and efficiency of fuel has a significant impact on this community. It is critical that we address both the economic and environmental effects of our oil dependence and take the steps to curb them both.

In order to address climate change, scientists have stressed the importance of achieving an 80% reduction in green house gas emissions by the year 2050. This means making small reductions in all of our emission areas, including transportation. United States????????? transportation sector amounts to approximately 20% of our total green house gas emissions. Therefore, properly measuring our progress requires considering reductions as a portion of that 20%, not as part of global emissions. In this light, every small improvement makes a difference.

If we were to take advantage of our best and most feasible technology, we would be in a position to reduce our oil use in addition to lessening the impact that the price of gasoline has on families like mine. NHTSA?????????s current proposal hinders this potential. Your analysis uses assumptions for future gas prices that are simply unrealistic. Today Americans are paying nearly $4 per gallon, and there is currently no reason to expect prices to drop as low as $2.25. Basing decisions on faulty analysis is irresponsible and disregards NHTSA?????????s duty to impose feasible fuel economy standards.

I urge NHTSA to consider how this rulemaking increases the strain on the average family and to reevaluate their position on this issue and on climate change at large.

Comments to the U.S. Department of Transportation
National Highway Traffic Safety Administration
at the Public Hearing on the Draft Environmental Impact Statement for New Corporate
Average Fuel Economy Standards,
Passenger Cars and Light Truck, MY 2011-2015

Submitted by Tara C. Morrow
August 4, 2008

Good morning. Thank you for the opportunity to speak today on this DEIS. My name is Tara Morrow and I am the Communications Director for Greater Washington Interfaith Power and Light. We are one of twenty-eight Interfaith Power and Light organizations across the U.S., a growing movement of people of faith responding to global warming.

When religious people talk about responsible stewardship of our resources or care of the earth, it is toward abundant life for future generations that they measure the costs to their own lives. As you set standards to meet the Energy Independence and Security Act's mandate to achieve a fleet wide fuel economy average of at least 35 mpg by 2020, may you remember that 35 mpg is a minimum and future generations will applaud us for our boldness in implementing what is technologically feasible or wonder how we lacked the creativity and will to respond to global warming and the challenges of energy security.

I did study physics in college, which helps me get through the statistics and tables of the DEIS, but I am here today as a person of faith, in particular greatly concerned about the impact energy policies and activities resulting in increased global warming emissions have upon the poor and vulnerable. As was demonstrated during the aftermath of Hurricane Katrina and around the world in recent months with increased food prices, quantifying the impacts of global climate change is not simple and will only increase in value as we more fully grasp its consequences. The debate about whether climate change is real, or caused by human activity, is over and as I witnessed from first-hand accounts during a recent trip to the Philippines, the effects are already taking a toll upon our world. While I was glad to see that the DEIS does assign a dollar value, greater than zero, to CO_2 reductions, I ask you to take another look at the value range and price carbon more accurately given the most recent analysis. The costs of global warming exacted on us, or more accurately on our children and grandchildren and generations to come, if we take only token action now is sure to be steeper than any costs incurred now.

Another matter for closer examination is the estimate of the price of gasoline used to determine what is then cost-effective. An assumption of $2.25 per gallon in 2016, in 2006 dollars, seems unrealistic given current realities – at least given what I paid yesterday on my way back from a family reunion in Pennsylvania. When higher projections of gas prices are used, then significantly higher standards are technologically feasible and economically practical.

Given the recent soaring gas prices, we are seeing a change in the market by consumer demand for vehicles with greater fuel economy. However I think the American people are ready for bold action – at least my generation is - and moving forward will take more than responding to market research. It takes full measure of the costs to us if we do not take action or take only very modest action, costs which the DEIS begins to address but I hope will be more fully incorporated when the final fuel economy standards are issued for passenger cars and light trucks for 2011-2015.

Comments on the Draft Environmental Impact Statement for New Corporate Average Fuel Economy Standards, Passenger Cars and Light Trucks, MY 2011-2015

National Highway Traffic Safety Administration

Docket No. NHTSA-2008-0060

I respectfully submit the following comments on NHTSA's DEIS for "Average Fuel Economy Standards for Cars and Light Trucks – Model Years 2011-2015"

I submit these comments as representing the interests of my two under-aged children. My comments relate primarily to the issue of GHG and the issue of climate "tipping point" raising the potential of premature death of my children, the possible extreme degradation of the planet they live on, and the possibility of such "tipping point" issues reducing the choices they have to bear their own children (who would be my grandchildren) and raise those children to have a happy, complete, secure life. My comments relate to reasons why NHTSA has set GHG CO2 emissions standards too high and how and why NHTSA should fix these regulatory errors.

*EIA Estimates of future gas prices are not rational estimates given the recent run-up in gas prices. The EIA estimates can be compared to the estimate of future gas prices implied in the short-term and long-term NYMEX oil and gas futures. If the EIA Estimates were correct estimates, and the NYMEX futures greatly differ [which they do] then that difference represents an arbitrage opportunity that traders can exploit, which in turn would drive NYMEX prices back to EIA Estimates. (Modern Arbitrage Theory) This hasn't happened. The conclusion is that EIA Estimates cannot be current rational estimates. See attached graph. Based on NYMEX future estimates of gas prices during the regulatory time frame I suggest that NHTSA adopt its "HOP – High Oil Price" scenario rather than its current "MOP – Moderate Oil Price" scenario. Or use NYMEX futures values directly rather than outdated EIA estimates.

*Truck CAFÉ curves cross Car CAFÉ curves. See attached graph. For several years at medium values of footprint NHTSA compliance curves set lower values for Cars than for Trucks. Since the MPG values for trucks have historically been set lower than cars because of the unique challenges and abilities trucks have, including greater hauling capacity and greater towing capacity, inverting this relationship never makes sense. This problem is part of a larger problem that NHTSA have largely designed the curves for cars and trucks independently when instead NHTSA needs to recognize that both consumers and manufacturers have the choice of car vs. truck. Thus the curves for cars and trucks need to be designed in a consistent and rational manner to work together. For example the great disparity between car and truck curves for small footprints should encourage manufacturers to design "AMC Eagle" style small "trucks" which have car-like characteristics except for being high and needlessly unstable, leading to unnecessary rollover fatalities. NHTSA's choice of design curves for cars vs. trucks works directly against NHTSA's charter of Highway Safety while resulting in greater GHG.

*CAA Preemption. NHTSA assertion of preemption is not rational for several reasons. First, NHTSA's proposed standards do not actually regulate GHG tailpipe emissions. Rather NHTSA sets relationships between tailpipe emissions and footprint. NHTSA does not know how much GHG will be emitted because it will depend on the actual mix of car, trucks, and their footprints. States might set rules that tend to affect this mix or limit GHG which would not stop NHTSA for setting whatever GHG/footprint, car vs. truck relationships NHTSA want. Secondly, Congress specifically prevents NHTSA from consideration of alternative fuels, which states might use in their regulations to limit overall GHG net emissions. For example California might set regulations designed to make 10% of their autos electric powered by green electricity, thereby reducing GHG emissions by 10% compared to federal regulations.

*Kahane: NHTSA continues to misinterpret the results of Kahane exactly backwards. Kahane's studies illuminate nothing about how manufacturers might actually design new vehicles to achieve higher fuel economy. For hypothetical example a vehicle redesigned to have a carbon fiber body with the same stiffness but lower weight might have higher fuel economy AND greater safety. We don't know. Nothing in the Kahane studies comes close to addressing these kinds of engineering design tradeoffs. But on the contrary, Kahane *does* well-model the scenario where in the face of high gas prices consumers are on average forced within an existing market mix of vehicles to purchase slightly smaller vehicles in order to achieve affordable fuel economy when facing a market where NHTSA and Manufacturers have failed to provide vehicles with fuel economy matching market gas prices. NHTSA then, should be looking to Kahane to illuminate the excess deaths caused to consumers when NHTSA sets fuel economy standards too weak in the face of high gas prices. Such a failure to regulate, and the excess deaths that result, represent a direct failure of NHTSA to meet its primary mandate of Highway Safety. Weak Fuel Economy Standards Equals Excess Traffic Deaths. Not the other way around. Consumers need to be able to buy the fuel economy they need in the vehicle size they want without being forced to downsize due to NHTSA setting fuel economy standards that are too weak. Continuing to read Kahane "backwards" results in setting GHG emissions standards too high.

*Fuel Economy Advertisements: Manufacturers are widely misrepresenting EPA Fuel Economy values on TV by quoting highway mileage values as-if they are combined mileage values. NHTSA need to act to correct these deliberately distorting practices. These advertisements are in turn representative of the fact NHTSA has been setting fuel economy standards too low, forcing manufacturers to misrepresent to the public how they have chosen to implemented those standards. Allowing these advertising deceptions results in higher GHG.

*Bias in the High Threshold transition point of the truck curves. NHTSA has lowered the high point threshold in the truck curves without a rational basis for doing so. Having incomplete information on the subject means choosing a best estimate, not biasing that estimate. Biasing this threshold results in greater GHG, and reduces most consumers ability to choose a rationally size vehicle to meet their family's needs without fear of death in collisions with those large trucks that the biased high threshold encourages, which again increases GHG.

*"Divide and Conquer" NHTSA's analysis of GHG emission from cars and trucks which only looks at US cars and trucks, only looks at the regulatory delta of those cars and trucks, and only looks at the US part of the SCC value of those cars and trucks is a case of "Divide and Conquer" where each regulatory agency of the government claims its actions are small enough to be considered "negligible" in the global context, whereas the reality is that GHG pollution from cars and trucks worldwide represents a large fraction of the entire GHG problem. On the contrary, NHTSA should be considering vehicle GHG emissions as being part of an overall scheme necessary to reduce total GHG emissions in the US and around the world. For example, if GHG is reduced by 10% by NHTSA's regulations, consider if this was part of scheme to reduce total GHG emissions by 10% in the US, and around the world.

*"Cowboy Diplomacy" NHTSA's analysis of GHG emissions assumes implicitly these regulatory changes only affect the behavior of vehicles in the United States. However most manufacturers are world-wide and can be expected to apply developed technology world-wide. Further, if the US reduces GHG emissions from vehicles that should be expected to engender at least some amount of goodwill "diplomatic synergy" with other nations, particularly with Europe. If the US reduces vehicle GHG Europe can also be expected to reduce vehicle GHG. If a 10% reduction in US vehicle GHG resulted in a 10% reduction in European vehicle GHG one would have 100% diplomatic synergy between the regions. NHTSA is currently assuming implicitly 0% diplomatic synergy, IE "Cowboy Diplomacy" where the US acts alone without any other nation following suit. Since both major candidates for the presidency during the years of these regulations have pledged better cooperation with other nations NHTSA should be assuming something more than 0% diplomatic synergy. Further, US GHG reductions from vehicles can be a starting point for cooperation in reducing GHG in other areas, increasing even more the "diplomatic synergy." NHTSA implicitly is assuming a value of 0% for all these synergies when NHTSA rationally should be expecting a higher value.

*Plug-in hybrids. Given GM commitment to delivering a plug-in hybrid (Chevy Volt) in this time frame, NHTSA's assumption that plug-in technology will not exist during the regulatory period is troubling, and will lead to higher GHG.

*Start/stop mild hybrid on small cars. NHTSA's assumption that this technology is not available for small cars is troubling given that it has already been implemented in Europe (Smart Fortwo mhd.) This assumption results in higher GHG.

*Uncertainty in future gas prices and GHG understanding. Given the uncertainty in future gas prices, as evidenced by the disparity between the EIA values NHTSA has used vs. recent gas prices, and recent large decreases in the estimated GHG concentrations necessary to reach tipping point [http://www.columbia.edu/~jeh1] NHTSA should reduce the numbers of years its proposed regulations extend forward. The farther one projects into the future, the greater the error in these projections. Given the rapid changes in our understanding of Global Warming and GHG, and the rapid changes in gas prices, it would be rational to extend the regulations forward for fewer years, allowing NHTSA to respond more appropriately once better understanding of these issues have been reached.

General Comment

Comment My name is Elizabeth McGurk. I am here because as a person of faith and an employee of the National Council of Churches in Christ, I recognize that we al have a
responsibility to be stewards of God's world and to care for one another. Achieving
higher fuel economy standards for U.S. cars and trucks is one of the most important
actions we can take to reduce our greenhouse gas emissions which are causir global
warming and impacting both God's people and God's planet. Increasing Corpc Average Fuel Economy (CAFÉ) standards is a critical step that must be taken reduce pollution and curb greenhouse gas emissions that cause global warmir while
protecting those who already suffer from high gas prices. Improved CAFÉ standards
would mean more vital discretionary income for low-income working families spend
on necessities like food, health care, and housing. Significantly improving CAF standards will also reduce U.S. dependence on oil and decrease the need to o sensitive wilderness areas including the outer continental shelf to oil and gas exploration.

As a native Floridian, I know too well that our communities are already begin to feel
the effects of global climate change. During my freshman year at Eckerd Colle in
St. Petersburg in 2004, we were evacuated four times in one month for four different
hurricanes. I am worried about the ways in which global climate change and c country's dependence on extractive non renewable resources will affect my h state
and my friends and family members living there. I know that the costs both tangible and
intangible of doing nothing will far exceed the cost of taking preventive action Your environmental impact statement should take into consideration the environmental
benefits of increasing CAFÉ standards in their entirety. For this reason, I urge to
strengthen the current proposed standards by setting a new standard of at le 35mph
by 2015.

Genesis 2:15 calls us to "till and to tend the garden." Toward that end, we ha moral
obligation to choose the safest, cleanest, and most sustainable sources of ene to
protect and preserve God's creation. God calls on us to be wise caretakers of Earth's gifts—protecting air and water quality, as well as ecosystems and hum communities. Good stewardship includes reducing, to the greatest extent possible, the
human-generated carbon dioxide emissions that are causing global warming.

Thank you.

Elizabeth McGurk

NHTSA-2008-0060-0555.1 **National Council of Churches Eco-Justice Program - Comment**

Acc. No. 0555.1

July 18, 2007

Dear Representative:

As people of faith, we are called to "till and to tend the garden" (Gen 2:15). Toward that end, we have a moral obligation to choose the safest, cleanest, and most sustainable sources of energy to protect and preserve God's creation. Thus, on behalf of the religious organizations we represent, we urge you to increase the Corporate Fuel Economy (CAFE) standards of America's vehicles and increase the percentage of renewable energy used in the United States.

God calls on us to be good caretakers of the Earth's gifts—protecting air and water quality, as well as ecosystems and human communities. Good stewardship includes making timely investments in renewable energy technologies, increasing the percentage of renewable energy used in the United States, and increasing fuel efficiency.

By reducing our use of carbon-based electricity through the use of renewable energy, we can also reduce our carbon dioxide emissions. In the U.S., the largest source of carbon dioxide emissions that cause global warming is the electric power industry, accounting for about 40 percent of all U.S. emissions. More than 80 percent of these emissions come from older, dirtier coal-fired facilities. Additionally, these power plants are a source of nitrogen oxide and sulfur dioxide, which cause smog, asthma and other breathing-related illnesses, and mercury exposure which causes birth defects.

Increasing CAFE standards is another critical step that must be taken to reduce pollution and curb greenhouse gas emissions that cause global warming. Improving CAFE standards will also decrease U.S. dependence on oil and decrease the need to open sensitive wilderness areas to oil and gas exploration. Higher fuel economy standards would also benefit our families and our communities by reducing the burden of high gas prices. This would mean more vital discretionary income for low-income working families to spend on necessities like food, health care, and housing.

As people of faith, we have long recognized our responsibility to be stewards of God's creation. As individuals, congregations, and communities, we are committed to pursuing God's vision of a restored creation. To do so requires a change in current patterns of behavior and a reordering of our priorities as a nation. As representatives of the faith community, we urge you to adopt a national energy policy based upon the values of justice and sustainability. Any renewable energy standard must rely on energy options such as wind, solar, geothermal and biomass – resources that are clean and sustainable while moving our country away from coal and other fossil fuels.

We urge you to support a renewable energy standard and higher CAFE standards that will protect human health, increase our energy security, and curb the warming of the earth which threatens all of God's creation. Taking such action is a way to act upon the faith-filled call to love, preserve, and protect the integrity of God's creation.

General Comment

Comment August 14, 2008

NHTSA

Dear NHTSA,

I feel very strongly about this issue both as a citizen concerned about global warming, and as a consumer dealing with high gas prices.

Global Warming is happening Right Now. Reducing green house gas emission by 2050 will save us from the worst effects of global warming. Unfortunately, we've all noticed 80% is a lot.
Increasing CAFÉ standards will not achieve this. In fact, no individual sector could reach such a dramatic decrease. This is why we must strive for smaller, achievable decreases in all sectors. These small decreases combined could ma substantial difference.

There is no point doing nothing, giving up, and ruining the planet for future generations – for my generation and our children - simply because increasing CAFÉ standards alone won't make the required difference.

This is a simple step. Let us prove that the United States does have the technology to do this. Let us set a good example for other nations. We worry about China and India developing and the added pollution that will cause. Let pave the way towards a solution.

Fuel economy standards are already higher in Europe than in the U.S. So, the technology is available. The industry feels threatened by the changing of the status quo, and opposes these higher fuel economy standards. Just like the industry opposed seatbelts. Just like the industry opposed airbags. But seatbelts and airbags did not hurt the auto industry, and neither will increase CAFÉ standards. In fact, with the price of gas over $4 a gallon, consumers are looking for fuel efficient vehicles.

If saving the environment isn't an important enough reason, if having a safe, non-hazardous planet for future generations to live on isn't enough motivatio increase CAFÉ standards to save our wallets.

Higher gas prices increase the price of going to work. People need to pay exorbitant amounts of money just to make money.
People pay more for food that needed to be transported.

Sen. Mikulski from Maryland said that when Bush took office, the average fan spent a little over $3000 a year on gas. Now, that average family spends $50 and pays more for food too. $2000 sends a kid to a community college for a y $2000 can alter a family's lifestyle.

We pay too much for gas and more drilling is not the solution. People have be warning for years that there is a finite supply of oil. Even if we grant oil companies new leases for drilling, it will be 10 years before oil from those leases will be pumped into your car.
Even if we drill more, we will still not produce enough to satisfy U.S. demand. We will still depend on foreign nations for oil. We will still risk our national security for oil.
Even if we drill more now, there will still come a time when the world's supply of oil runs out.

We must fight our addiction to oil. Reduce our oil consumption so that when t day comes, the United States' economy will not crash. Agriculture, industry, transportation and services will continue using alternative energy sources. Th is not a transition that can happen over night. We cannot wait for the world to run out of oil to begin looking for alternatives. This must be a gradual transition.

So, why not start by improving CAFÉ standards?

Thank you for your time.

Sincerely,

Catherine Easton

COMMENTS ON:
Draft Environmental Impact Statement
Corporate Average Fuel Economy Standards, Passenger Cars and Light Trucks, Model Years 2011—2015

Department of Transportation,
National Highway Traffic Safety Administration
Docket No. NHTSA—2008—0060

Submitted by
Luke Tonachel, Vehicles Analyst
Brian Siu, Policy Analyst
for the
Natural Resources Defense Council (NRDC)
on
August 14, 2008

The Natural Resources Defense Council (NRDC) is pleased to provide comments to the National Highway Traffic Administration's (NHTSA) Draft Environmental Impact Statement (DEIS) for Corporate Average Fuel Economy Standards for Passenger Cars and Light Trucks, Model Years 2011—2015.

NRDC respectfully disagrees with the NHTSA's characterization that the environmental impacts of the evaluated alternatives are small and difficult to distinguish. When considered in the context of multiple strategies to cut global warming pollution and avoid dangerous climate change, a standard of at least 35 miles per gallon (mpg) for model year 2015 results in very significant benefits over the NHTSA's proposed standard of 31.6 mpg. The time for strong action on global warming is now and more aggressive fuel economy standards must be part of that action to ensure that passenger vehicles remain on a reasonable trajectory to the much higher levels of fuel economy that will be needed to meet 2050 climate stabilization targets.

The DEIS is further deficient because it evaluates invalid CAFE alternatives. The alternatives are derived from a NHTSA's CAFE rule that proposes unlawful fuel economy levels because they fail to meet the test of maximum feasible. As explained in

NRDC's comments to the Notice of Proposed Rulemaking (NPRM), Docket 2008-0089, NHTSA used faulty methodology and assumptions that resulted in an unlawfully weak CAFE standard. To provide the impact of new fuel economy standards, the DEIS must evaluate valid CAFE alternatives.

Our comments are provided in more detail in the following sections.

NHTSA Should Evaluate the Impact of CAFE Alternatives in the Context of the Multiple Strategies to Cut Global Warming Pollution

In the DEIS, NHTSA characterizes the differences in the environmental impacts between the proposed standard and the other evaluated alternatives as small and difficult to distinguish. The fuel economy level proposed by NHTSA in the CAFE rule, referred to as the "Optimized" alternative in the DEIS, reaches a fleetwide fuel economy level of 31.6 mpg in for model year (MY) 2015. Other alternatives reach higher levels; for example the Total Cost Equals Total Benefits (TC=TB) alternative reaches 37.5 mpg for MY 2015. The DEIS concludes that there is almost no difference between the proposed standard and the TC=TB alternative, noting that the two alternatives differ by only 0.2 percent in terms of global warming emissions reductions in 2100. Our analysis of similar alternatives shows that NHSTA's characterization is misleading. In reality, more aggressive alternatives to the proposed rule can have very significant environmental benefits over the proposal. For example, a standard that reaches 35 mpg with MY 2015 instead of MY 2020 could save more than a billion barrels of oil and cut greenhouse gas (GHG) emissions by more than 510 million metric tons of CO_2-equivalent (MMTCO_2e) by 2020. A 35 mpg standard for MY 2015 would also pave the way for future fuel economy increases beyond 2015; these increases would put the U.S. on a path to achieve at least 40 mpg by 2020 and provide further oil and GHG savings not envisioned by the current DEIS.

The inability to differentiate the impacts among alternatives is the result of NHTSA's failure to consider light-duty fuel economy increases in the context of other measures designed to reduce global warming pollution. Fuel economy standards must be evaluated in the context of a comprehensive package of emission reduction measures needed to meet GHG emission reduction targets necessary to solve global warming. To draw an analogy, when a state must clean up its air to meet national ambient air quality standards, a State Implementation Plan, or SIP, must be submitted to EPA describing how pollution reductions will be achieved from a package of regulations on vehicles, fuels and consumer products. To solve global warming, GHG emission reductions are needed beyond the transportation from other energy-intensive sectors of the economy including power generation, industrial, commercial and residential sectors. When considered alongside measures in other sectors, it is clear that fuel economy standards play a critical, substantial role in avoiding dangerous climate change and more stringent standards are critical for achieving the necessary global warming pollution reductions in the transportation sector.

The weak passenger vehicle standard proposed by NHTSA for MY2011-MY2015 does not ensure that vehicle fuel economy levels will be on a continuous, smooth trajectory to meet the longer term fuel economy necessary to achieve 2050 GHG emission reduction targets. This introduces serious risk because the necessary trajectory gets steeper and steeper the longer we wait.

Reducing global warming pollution 80 percent by mid-century will require the United States to substantially transform its energy economy. NRDC examined multiple strategies to reduce global warming pollution on both the demand (energy consuming) side and the supply (energy producing) side of the equation and pinpointed six major groups of energy sector opportunities that will put America on the path to significantly reducing the pace and magnitude of global warming.[1] In this context, fuel economy standards are a very significant strategy for reducing U.S. emissions. As shown in Figure 1, when combined with smart growth measures, improved vehicle efficiency can contribute 13% of total reductions needed.[2]

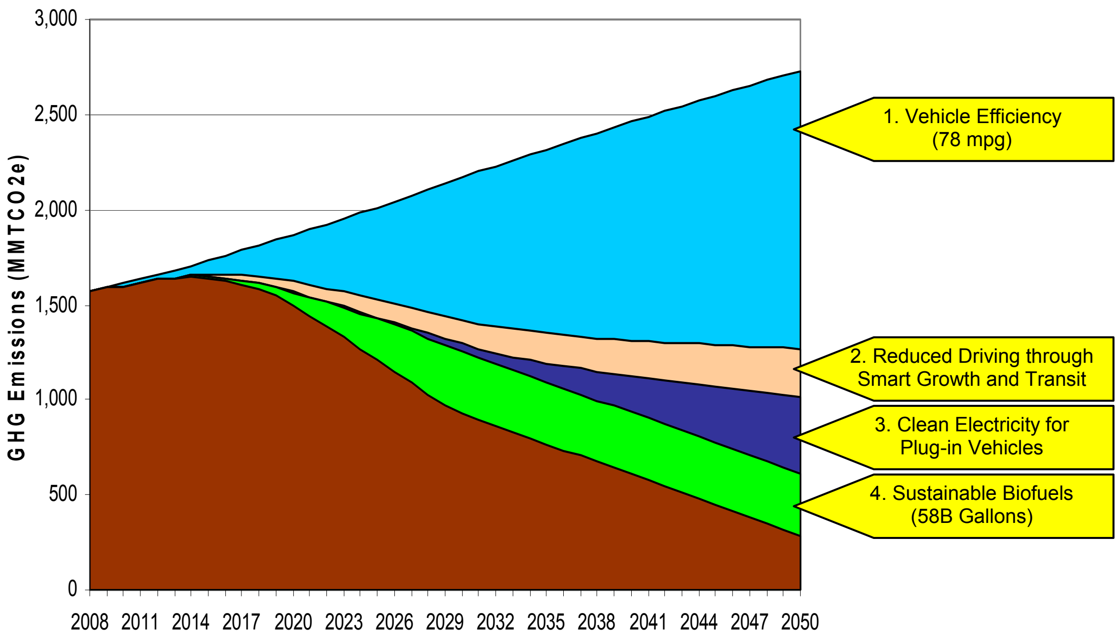
Figure 1: Six Opportunities for Reducing U.S. Fossil Fuel Emissions

		Carbon Pollution Avoided by 2050	Percent of Total Needed by 2050
1	Building efficiency to reduce heating and electricity needs.	1.7 billion tons	16%
2	Vehicle efficiency and smart growth communities to help cars go farther on less fuel and reduce vehicle travel.	1.4 billion tons	13%
3	Industrial efficiency such as combined heat and power to reduce industrial energy use.	1.2 billion tons	11%
4	Renewable electricity from sources such as wind, geothermal, and solar power, which have the potential to supply 40 percent of our energy needs.	1.4 billion tons	13%
5	Low-carbon transportation fuels such as biofuels made from crop waste and switchgrass to replace imported oil.	1.1 billion tons	10%
6	Carbon capture and storage of CO_2 emissions from coal-fired power plants in geologic structures deep in the earth, where it is gradually absorbed.	1.1 billion tons	10%
		TOTAL: 7.9 billion tons of carbon pollution avoided	**TOTAL: 73% of total emissions reductions needed**

[1] These measures achieve three-quarters of the reductions needed by 2050. The remainder would come from non-CO2 gases, forestry measures, and innovations to address thousands of smaller sources.
[2] Chart from NRDC Issue Paper, "The New Energy Economy: Putting America on the Path to Solving Global Warming," June 2008. Available at http://www.nrdc.org/globalWarming/energy/contents.asp.

In terms of the transportation sector alone, fuel economy improvements comprise an even larger share of the GHG reductions. NRDC estimates that improved efficiency can contribute nearly 60 percent of the cumulative GHG reductions needed from the passenger vehicle sector. As shown in Figure 2, achieving 80% reductions from current emissions in the light-duty vehicle fleet requires a combination of improved fuel economy, smart growth, increased transit investments and a transition to low carbon alternative fuels such as electricity and biofuels. Without significant and early GHG reductions from greater vehicle efficiency, achieving the 80 percent reduction target becomes extremely challenging, if not impossible.

Figure 2: Four Key Strategies for Achieving 2050 80 Percent Reduction Climate Stabilization Target for Light-Duty Vehicles



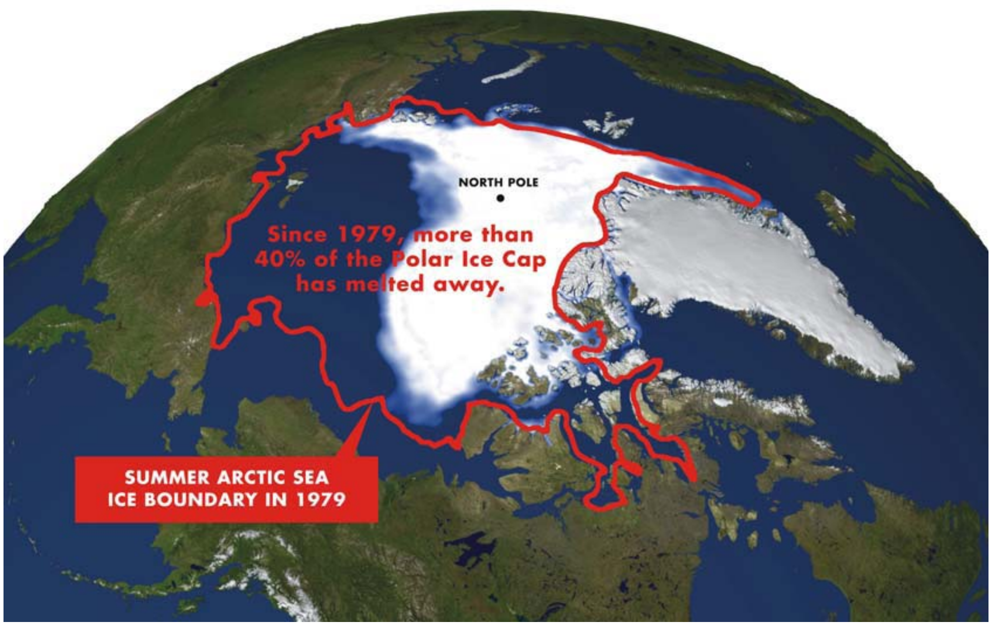
To Avoid Dangerous Climate Change, the U.S. Must Act Today to Implement All Cost-Effective Technologies that Reduce Global Warming Pollution

More stringent alternatives to NHTSA's proposed fuel economy levels result in larger GHG reductions sooner. Furthermore, earlier action provides greater certainty that the US will reach its mid-century GHG reduction target and avoid dangerous climate change. Early action relies on the use of existing cost-effective technologies and allows for a more gradual transition from today's energy infrastructure to low carbon resources. Because of the cumulative build-up of global warming pollution in the atmosphere, a slow introduction of technologies designed to reduce pollution makes avoiding climate change much more challenging.

Recent Congressional testimony by Michael Goo, NRDC's Climate Legislative Director, clearly describes the urgent need for aggressive action on global warming today. The testimony excerpted below was presented to the Subcommittee on Energy and Air Quality, Committee on Energy and Commerce, United States House of Representatives hearing on legislative proposals to reduce greenhouse gas emissions, June 19, 2008:[3]

> The time for action on global warming has already been delayed too long. Every day we learn more about the ways in which global warming is already affecting our planet. Recent satellite pictures show that summertime arctic ice has declined by 40 percent since 1979 (Figure [3]). The UN Intergovernmental Panel on Climate Change (IPCC) found that 11 of the past 12 years are among the 12 hottest years on record. The Greenland and West Antarctic ice sheets are losing mass at accelerating rates. Rising sea surface temperatures correlate strongly with increases in the number of Category 4 and 5 hurricanes. Increases in wildfires, floods and droughts are predicted to occur as global warming continues unabated. Our oceans are warming and becoming more acidic. Everywhere one looks, the impacts of a disrupted climate are confronting us.

Figure [3]: ARCTIC MELTDOWN - Arctic summer sea ice extent in 1979 and 2007.
Source: NASA.



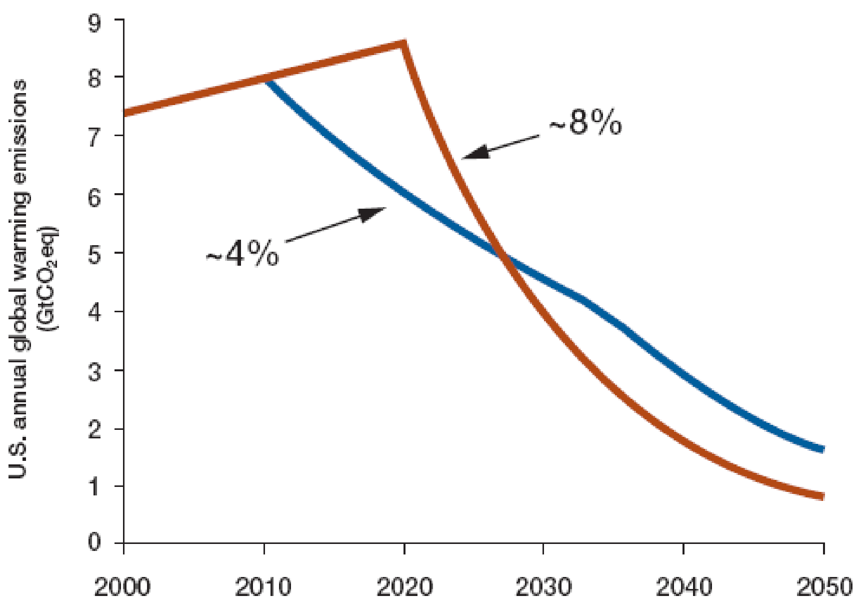
> Climate scientists warn us that we must act now to begin making serious emission reductions if we are to avoid truly dangerous global warming pollution concentrations. Because carbon dioxide and some other global warming pollutants can remain in the atmosphere for many decades, centuries, or even longer, the climate change impacts from pollution released today will continue throughout the 21st century and beyond. Failure to pursue significant reductions in global warming pollution now will make the job much harder in the future—both the job of stabilizing atmospheric pollution concentrations and the job of avoiding the worst impacts of a climate gone haywire.

[3] Full testimony available at http://docs.nrdc.org/globalWarming/default.xdl.

Since the start of the industrial revolution, carbon dioxide concentrations have risen from about 280 parts per million (ppm) to more than 380 ppm today, and global average temperatures have risen by more than one degree Fahrenheit over the last century. A growing body of scientific opinion has formed that we face extreme dangers if global average temperatures are allowed to increase by more than 2 degrees Fahrenheit from today's levels. We may be able to stay within this envelope if atmospheric concentrations of CO_2 and other global warming gases are kept from exceeding 450 ppm CO_2-equivalent and then rapidly reduced. However, this will require us to halt U.S. emissions growth within the next few years and then cut emissions by approximately 80 percent over the next 50 years.

This goal is ambitious, but achievable. It can be done through an annual rate of emissions reductions that ramps up to about a 4 percent reduction per year (see Figure [4]). But if we delay and emissions continue to grow at or near the business-as-usual trajectory for another 10 years, the job will become much harder. In such a case, the annual emission reduction rate needed to stay on the 450 ppm path would double to 8 percent per year. In short, a slow start means a crash finish, with steeper and more disruptive cuts in emissions required for each year of delay.

Figure [4]: SLOW START… CRASH (OR BURN) FINISH
Source: Union of Concerned Scientists.



To avoid the crash finish, the United States should act today to aggressively implement existing, cost-effective technologies to global warming pollution from all sectors. The NHTSA CAFE DEIS should distinguish how more aggressive alternatives to the proposed standard put the U.S. on a more certain path for solving global warming.

The Environmental Impact Assessment Should Evaluate a Valid CAFE Proposal and Alternatives; Faulty Methodology in the NHTSA Proposed Rule Means that the DEIS Findings Are Based on an Unlawful Proposed Rule

The Draft Environmental Impact Statement is inaccurate because evaluates an unlawful NHTSA CAFE proposal. As explained in NRDC's comments to the proposed rule, NHTSA failed to meet its statutory directive to set the maximum feasible fuel economy levels.[4] In calculating the required fuel economy level, NHTSA used erroneous assumptions for key input parameters and NHTSA set arbitrary limits on the availability of key vehicle technologies that could significantly improve fuel economy. These assumptions inaccurately characterized technologically feasible and economically practicable fuel economy in NHTSA's NPRM for both the proposed rule and the alternatives and therefore similarly skew the findings in the DEIS. Specifically, there are four main incorrect assumptions the agency makes: too low fuel prices, undervalued economic value of climate change oil externalities, too high of a discount rate, and undervaluation of economic values for military oil externalities. The agency also arbitrarily underestimated the availability of technology to improve vehicle fuel economy. In summary:

- NHTSA relies on the Energy Information Administration's Reference Case forecast for fuel prices. However, both the Reference and High Case forecasts have consistently underestimated fuel prices and NHTSA fails to use a reasonable forecast consistent with likely price trajectories.

- The social cost of carbon used by NHTSA is based on an arbitrary range of values and incorrectly relies on a central estimate of $7 per metric ton of CO_2. Unmitigated, costs of dangerous climate change are very likely much higher than estimates in standard literature, and NHTSA must use a reasonable risk premium in its calculations.

- NHTSA fails to adhere to standard economic practice and governmental guidelines when it used a discount rate of 7 percent. The agency should use a discount rate that does not exceed 3 percent and should conduct sensitivity analysis for even lower values.

- The economic value of military security to protect oil supplies should be non-zero and positive. When NHTSA used zero it ignored the U.S. military security-related benefits of reduced oil consumption, such as enhanced flexibility to respond to supply threats and move the country in the direction of oil being a nonstrategic resource.

---

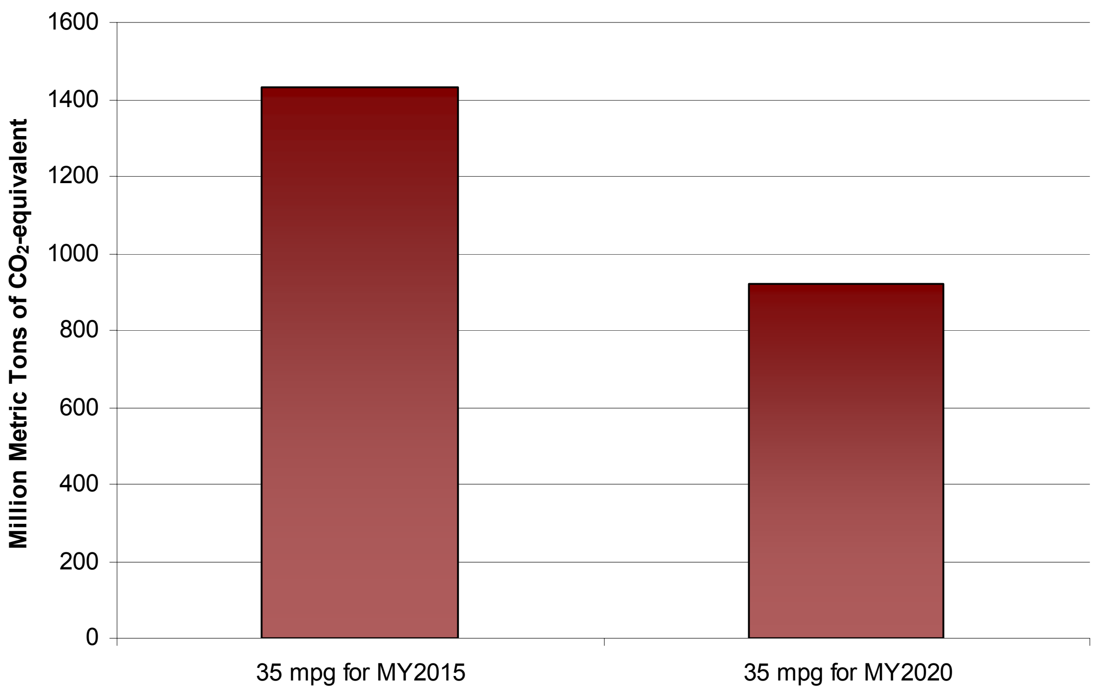
[4] NRDC, "COMMENTS ON: Notice of Proposed Rulemaking, Average Fuel Economy Standards, Passenger Cars and Light Trucks; Model Years 2011—2015, Department of Transportation, National Highway Traffic Safety Administration, Docket No. NHTSA—2008—0089," submitted July 1, 2008.

- NHTSA set arbitrary limits on technology availability in the Volpe Model, which biased toward setting a weaker fuel economy standard. Two specific examples include an arbitrary constraint on the use of lightweight materials substitution to improve fuel economy and the exclusion of plug-in hybrid electric vehicles from consideration in the Volpe Model.

If NHTSA had used reasonable assumptions for their analysis, the fuel economy levels in the proposed rule and all cost-dependent alternatives would be higher. For example, based on NHTSA's *own* sensitivity analysis presented in the Preliminary Regulatory Impact Assessment, the MY2015 fuel economy standards should be set at least at the level that would result in a combined fleet average of 35 mpg by MY2015 if the fuel savings are more properly valued.

The potential additional public and private benefits of raising the standards to 35 mpg by MY2015 are enormous. Consumer pocketbooks, the nation's energy security, and the environment would all stand to benefit tremendously from a 35 mpg standard. We estimate by 2020, the U.S. would conserve 3 billion barrels of oil, 1.5 times more, if the MY2015 standard was set at a level that resulted in a combined 35 mpg instead of 31.6 mpg. The 35 mpg level in MY2015 also avoids 510 million metric tons of global warming pollution (see Figure 5).

Figure 5: Cumulative Global Warming Pollution Reductions in 2020



NRDC calculation using the Long-range Energy Alternatives Planning (LEAP) system stock model (available at http://www.seib.org/software/leap.html) to estimate on-road fleet fuel economy. Savings for each scenario are in relation to a baseline using vehicle populations and mileage for 2005 to 2030 provided from in EIA's Annual Energy Outlook 2008. Baseline new passenger car and light truck fuel economy are held constant at the 2010 level from 2011 to 2030.

The emissions reduction estimates are conservative, however. Beyond 2015, the fuel economy standards could continue to increase to over 40 mpg in 2020, which would result in even greater pollution reductions.

The Draft EIS must evaluate a lawful proposed rule and compare it against reasonable alternatives. In the case of this DEIS, NHTSA has failed to evaluate a maximum feasible standard and a consistent breadth of alternatives based on reasonable assumptions.

General Comment

Comment Taking actions that reduce American's dependence on oil and set us on a path a clean energy future are matters of environmental justice and NHTSA has an obligation to increase fuel economy standards to the maximum feasible in ord to save Americans money, eliminate our addiction to oil, and protect the environment.

RE: Draft Environmental Impact Statement for New Corporate Average Fuel Economy Standards, Passenger Cars and Light Trucks, MY 2011-2015

NESCAUM (Northeast States for Coordinated Air Use Management) submits the following comments on NHTSA's Draft Environmental Impact Statement (DEIS). NESCAUM is an association of state air pollution control agencies in Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Rhode Island, and Vermont. Please note that NESCAUM recently submitted comments to the docket[1] on the NHTSA's Proposed Rule for Average Fuel Economy Standards. NESCAUM incorporates by reference our previous comments pertaining to the DEIS in that proposed rule.

In our previous comments, we noted that the Proposed Rule was published on May 2, 2008 with a deadline for comments of July 1, 2008, but NHTSA did not release the DEIS until June 24, 2008. Consequently, there was little opportunity to consider the DEIS while reviewing and developing comments on the Proposed Rule. The applicable federal regulations state, "NEPA procedures must insure that environmental information is available to public officials and citizens before decisions are made and before actions are taken."[2] Further, these regulations require federal agencies to "[i]ntegrate the requirements of NEPA with other planning and environmental review procedures…so that all such procedures run concurrently rather than consecutively." In so doing, the effect is to "[e]ncourage and facilitate public involvement in decisions which affect the quality of the human environment." Unfortunately, by separating the review periods for these two actions, the public involvement processes, both for the Proposed Rule and for the DEIS, were not well served.

NESCAUM's primary concern with the DEIS is with how it addresses cumulative effects, defined as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and *reasonably foreseeable* future actions regardless of what agency (Federal or non-federal) or person undertakes such other actions." (emphasis added)[3]. Noteworthy in this regard is the official NEPA guidance document, <u>Considering the Cumulative Effects under the National Environmental Policy Act</u>,[4] which makes a number of important points, including:

- The analyst's primary goal is to determine the magnitude and significance of the environmental consequences of the proposed action in the context of the cumulative effects of other past, present, and future actions.

---

[1] Docket ID No. NHTSA-2008-0089
[2] 40 CFR 1500.1 & 1500.2
[3] 40 CFR § 1508.7
[4] http://www.nepa.gov/nepa/ccenepa/ccenepa.htm

- The effects of a proposed action on a given resource, ecosystem, and human community include the present and future effects added to the effects that have taken place in the past.
- Individual effects from disparate activities may add up to or interact to cause additional effects not apparent when looking at the individual effects one at a time.

The DEIS, inconsistent with the regulations and policy guidance on cumulative effects, evaluates the effects of new CAFE standards without consideration of other important factors. For example, while NHTSA asserts the DEIS fully addresses foreseeable impacts through the year 2100, it errs by incorporating an assumption that technological improvements in fuel economy cease after model year 2020.[5] In reality and in contrast with this approach, technology-forcing requirements historically have spurred technological innovation to meet and even exceed environmental benchmarks. This interrelationship between policy initiatives and technology advancement has been well documented by numerous researchers[6] for more than thirty years and has even been given a name; *induced technological change.* There is little question that policies and legislative initiatives aimed at reducing carbon emissions are in our future, and these programs will create economic disincentives to continued business as usual, relative to consumption of fossil fuels in the transportation sector. Consequently and according to the principles of induced technological change, business and government will respond by engaging in more extensive research and development, including in the fuel economy arena, with a goal of reducing reliance on conventional fuels. As these research and development efforts bear fruit, technological progress will follow.

Given this principle of induced technological change, coupled with the underlying legislative requirement (i.e., the Energy Policy and Conservation Act – EPCA) for NHTSA to take a technology-forcing approach to future fuel economy requirements, further improvements beyond model year 2020 are, in fact, *reasonably foreseeable*. Thus, the approach taken in the DEIS disregards both precedent and the law. It is also important to note that economics by itself will play a future role, inducing technological change to improve fuel economy. The U.S. Energy Information Administration in its 2008 Annual Energy Outlook projects in its “high economic growth–high fuel price” scenario that between 2008 and 2030, energy use in the light duty vehicle sector will grow by 13 percent while at the same time, the price of gasoline will grow by 18 percent. As this scenario unfolds, there will be further incentives for investment into research and development for improving fuel economy. Therefore, NHTSA would do well to incorporate such economic factors into its cumulative effects analysis.

Despite these developments which call for bold policy steps to actively pursue significant improvements in fuel economy, NHTSA has chosen to pursue a very conservative course in setting near-term standards. We made this point in our comments submitted on the Proposed

[5] NHTSA’s apparent rationale is that the Energy Information and Security Act (EISA) mandates a fuel economy target that extends only through model year 2020.
[6] As a prime example, see Goulder, L.H., et al., Induced Technological Change and the Attractiveness of CO_2 Abatement Policies, *Resource and Energy Economics*, 21 (1999) 211-253.

Rule, noting NHTSA's initial consideration of seven different fuel economy stringency scenarios (ranging from no-action to technology exhaustion alternatives), and ultimate choice of an "optimized" alternative that maximized net benefits from an economic standpoint. In settling on this alternative for which there is little to no impetus for forcing technology, NHTSA's actions will have a dampening effect on progress toward long term improvements to fuel economy and by extension to progress addressing the environmental impacts brought about by climate change.

The DEIS, in its assessment of global benefits, also disregards the principle of technology transfer. If U.S. industries develop technology that markedly improves fuel economy, it's very unlikely that the technology will remain confined to the U.S. fleet. Ultimately, fleets worldwide will incorporate the same technologies. According to the World Resources Institute, energy consumption accounts for 61 percent of total GHG emissions and transport accounts for 22 percent of all energy consumption-related GHG emissions. U.S. transportation, according to the Energy Information Administration, accounts for 18 percent of global GHG emissions from petroleum consumption. Clearly, an aggressive program in the U.S. to markedly improve fuel economy, coupled with technology transfer, can be a key strategy for reducing GHG emissions globally.

The DEIS disregards these factors and NHTSA concludes that the standards will have a negligible impact on climate change. Quoting from the DEIS:

…because EISA requires average fuel economy of the passenger car and light truck fleet to reach a combined 35 mpg by 2020, the MY 2016-2020 CAFE standards are a reasonably foreseeable future action. Accordingly, the cumulative impacts analysis assumes the minimum MY 2016-2020 CAFE standards necessary to get to 35 mpg by 2020…Overall, the emission reductions for the MY 2011-2015 CAFE alternatives have a small impact on climate change. The emission reductions and resulting climate impacts for the MY 2011-2020 standards are larger, though they are still relatively small in absolute terms.

NHTSA's approach with the DEIS is unfortunately consistent with EPA's discredited argument in *Massachusetts v. EPA 127 S. Ct. 1438 (2007)* as to why that federal agency should not regulate GHGs emissions from new motor vehicles. EPA's rationale was that such regulations would have an insignificant effect on mitigating climate change. The Supreme Court rejected EPA's argument, pointing out that, "Agencies, like legislatures, do not generally resolve massive problems in one fell regulatory swoop. ('[A] reform may take one step at a time, addressing itself to the phase of the problem which seems most acute to the legislative mind' [internal citation omitted].)… And reducing domestic automobile emissions is hardly a tentative step… [T]he United States transportation sector emits an enormous quantity of carbon dioxide into the atmosphere."

In summary, NHTSA has an obligation to pursue a technology-forcing approach, as envisioned under EPCA, and address all *reasonably foreseeable* cumulative effects. The approach taken by NHTSA provides insufficient information to fully evaluate the fuel economy scenarios in the

DEIS. The DEIS overlooks the environmental harm of the less aggressive technology scenarios (including NHTSA's preferred option) caused by foregoing more technology-forcing alternatives having greater climate benefits. The failure to fully consider the reasonably foreseeable broad dissemination of advanced fuel efficient technologies is an informational lapse that needs to be more fully addressed. If you have any questions, feel free to contact Eric Skelton of my staff at (617) 259-2028 or eskelton@nescaum.org.

Sincerely,

Arthur N. Marin

Comment AJC TESTIMONY FOR AUGUST 4TH 2008
NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION (NHTSA) HEARING ON FUEL ECONOMY
ENVIRONMENTAL IMPACT STATEMENT

Thank you for the opportunity to speak before you today. My name is Ami Gr and I am the Energy Policy Specialist and Legislative Assistant for the Americ Jewish Committee which I am representing here today. We are the nation's o human relations organization with over 175,000 members and supporters represented by 31 regional chapters in the U.S., and 8 offices abroad.
AJC is a long-time advocate of the need to develop energy policy that will reduce our nation's dependence on foreign energy sources as well as protect environment. More then thirty years ago, prompted by the then-recent Arab embargo, AJC first adopted a policy statement on energy. Over the succeedin years, as the nation coped with an energy supply shock in the 70's, coupled w concerns about the environment, safety, and tanker dependency raised by th Exxon Valdez oil spill, AJC adopted and acted on several additional statement on energy policy. These statements reflected the agency's concern that our nation address its increasing dependence on imported oil, and the impact of t dependency on our economic health, and strategic and social stability, in a fashion consistent with protection of the environment and attention to policy impacts on the disadvantaged.
The 9-11 attacks against the U.S. underscored another crucial consideration, that our national security and our position as a world leader are seriously undermined by our dependence on foreign nations, many unfriendly or potent unstable, for a primary energy supply. Thus, just as this nation is taking extensive actions at home and abroad to protect the safety of our citizens, it is imperative that we take the steps necessary to enhance our national energ security.
As we have experienced in the past, energy prices have decreased for periods time, and with such fluctuations, Americans have become less sensitive to the need for this type of policy. Today, facing record prices at the pump, we feel that the need for further action on energy security is more urgent then ever, both by assuring safe and sustainable energy sources and through renewed attention to issues of conservation and efficiency.
While the U.S. comprises less then 5 percent of the world's population, it consumes approximately 25 percent of the world's oil. 2/3 of all oil consumed nationwide is for transportation - most of that for motor vehicles. A drop in domestic oil production, coupled with increased consumption, has created a scenario by which the U.S. is more reliant on foreign oil sources than ever before. As this trend continued, the U.S. has become even more reliant on oil from countries that have not traditionally been friendly to U.S. strategic interests and that have the potential to disrupt oil supplies worldwide, adversely affecting the world and U.S. economies with resulting lost jobs, a decreased quality of living, and harsher conditions for low-income families.
Dependence issues aside, climate change has the potential to disrupt our way life, irreversibly harm the natural environment, create ongoing humanitarian crises, and—because these changes may foster instability as societal demand exceed the capacity of governments to cope—undermine our efforts to keep ourselves safe and secure.

A majority of scientists today hold that climate change is attributable in large part to an increase in the volume of atmospheric greenhouse gases and that t gases are primarily a result of human activity, mostly CO_2 (carbon dioxide) fr combustion of fossil fuels.

The weight of the evidence demands, as a matter of prudence, that we devise policies directed at stemming climate change, as well as adapting to its reality. In urging these policies, we act in accordance with Jewish tradition, which commits us to the protection of life, stewardship of the earth and its inhabitants, and the well-being of future generations.

Last year, a historic step was taken when Congress passed, and President Bu signed into law the Energy Independence and Security Act that included, amo other provisions, a strengthening of Corporate Average Fuel Economy (CAFE) standards for the first time in more than two decades. We think that strengthening CAFE standards is one of the most crucial components of a multifaceted approach to drastically reducing our dependence on foreign oil, reduce our global warming emissions, save money at the gas pump and secu America's energy future. These new standards will save the United States. 1. million barrels of oil per day by 2020––approximately 40% of what we import the Persian Gulf.

In proposing a combined average of 31.6 mpg for Model Year 2015, NHTSA is failing to acknowledges the current technology that could safely and cost effectively make all vehicles reach a fleet wide fuel economy average of at least 35 miles per gallon by 2015. Further, the current proposal relies on fanciful gas price assumptions, which result in insufficient fuel economy levels. The proposal assumes future gasoline prices to be only $2.25 per gallo in 2016 (in 2006 dollars), when American consumers are already paying price nearly twice as much today. The use of below-cost energy estimates violates agency's statutory charter to impose mandatory maximum feasible fuel econo standards based upon a review of economic and technological feasibility.

NHTSA must reconsider the proposed standards and use its statutory authorit meet the urgent need of the United States to conserve oil and meet the curre growing demand of American consumers for vehicles that go farther on a gall gas. NHTSA should not conclude in its analyses that fuel economy gains are presumed to stop at 2020 levels, but further grow by means of using existing technologies. Furthermore, we see the use of alternative and renewable fuels new lightweight materials and electric powered vehicles taking up a bigger percentage of vehicle miles driven in the U.S. in the near future, further reducing our dependence on foreign oil and our GHG emissions.

We cannot overstate the importance of moving toward tougher fuel economy standards at this time, even as we should not underestimate the challenges t and other actions addressing energy security will entail. But we see no alternative if we are to put the United States on a more sustainable energy path, one that is essential both to our nation's security and our environmenta health.

- Remarks presented by Ami Greener, Energy Specialist at the Office of Government and International Affairs, American Jewish Committee.

COMMENTS ON THE DRAFT ENVIRONMENTAL IMPACT STATEMENT

of

AkPIRG, Arizona Consumers Council, Arizona PIRG, CALPIRG, Citizens' Utility Board of Oregon, Consumer Action, Consumer Assistance Council of Cape Cod, Consumer Federation of America, Consumer Federation of the Southeast, Consumers for Auto Reliability and Safety, Democratic Processes Center, Empire State Consumer Association, Florida Consumer Action Network, Florida PIRG, Illinois PIRG, Maryland Consumer Rights Coalition, Maryland PIRG, Massachusetts Consumers Council, New Jersey Citizen Action, New Mexico PIRG, NYPIRG, The Consumer Alliance, USPIRG, Utility Consumers Action Network, Victims Committee for Recall of Defective Vehicles, Virginia Citizens Consumer Council, VPIRG, Wisconsin Consumers League

Mark Cooper
Director of Research
Consumer Federation of America
2000 L Street N.W.
Washington, D.C.

August 18, 2008

The Consumer Federation of America and 27 of its member groups appreciate the opportunity to file comments in the above captioned docket. The groups filing these comments are from fifteen states and focus on a wide range of public policy issues, but they all recognize the vital importance of fuel economy standards for America's energy future. We believe that raising fuel economy standards must play a critical role in reducing the nation's oil addiction, enhancing national security and protecting the environment. We are deeply disappointed by the failure of the National Highway Traffic Safety Administration (NHTSA) to raise the standards to a level that reflects the severe energy situation and the current auto market reality in the United States. NHTSA has failed to set standards at the maximum feasible level, denying consumers and the nation over 150 billions of gallons of gasoline savings in the next decade. As the attached study prepared by one of the consumer groups shows, NHTSA has completely misjudged the consumer and the auto marketplace and proposed a standard that is far too low. The draft environmental impact statement suffers from the same basic flaws that afflict the proposed rule.

Many of the issues discussed below have been addressed in prior comments filed in this rulemaking, but recent events have made the flaws in NHTSA's analysis and framework so much more obvious that we feel obliged to restate our objections to the proposed rule and incorporate that new evidence into the record. Our recommendations mirror earlier recommendations of consumer advocates in this proceeding. In order to propose a reasonable standard that fulfills the goals of the statute, NHTSA must:

- Raise the proposed standards for 2011 and 2012; and
- Withdraw the proposed standards for 2013 through 2015, so it can fix its faulty analytical framework and economic assumptions.

In light of the new evidence on the swift changes by consumers to embrace more fuel-efficient vehicles, we believe that the standard should be set at the highest level in NHTSA's analysis that was economically practicable.[1] This would raise the standard for 2011 to 30.6 miles per gallon, from the proposed level of 27.8 mpg. The attached report shows that consumers are more than willing to purchase such vehicles and the dramatic changes that the automakers have announced in their product plans indicate they can deliver the vehicles necessary to achieve this level of fuel economy.

THE PROPOSED RULE AND ITS ENVIRONMENTAL IMPACT STATEMENT FAIL TO ACHIEVE THE GOALS OF NEPA AND EPCA

There are two problems in the draft environmental impact statement that render it woefully inadequate to address the public policy goals of the National Energy Policy Act and the Energy Policy Conservation Act.

First, the analysis underlying the proposed rules is so fundamentally flawed that the agency has not considered an appropriate range of policy options, for which the environmental impact should be evaluated. Erroneous assumptions about market fundamentals have led NHTSA to center its analyses on a level of fuel economy that is so low that it sheds little light on what the environmental impact of a reasonable fuel economy standard would be. NHTSA has based the proposed rule on flawed assumptions and data on:

- Consumer behavior and attitudes toward fuel economy;
- Automaker capabilities to incorporate fuel savings technologies; and
- The price and value of energy.

[1] This is the point in the initial analysis where total benefits equal total costs. When NHTSA corrects the many flaws in its approach benefits from this level of fuel economy will far exceed the costs

NHTSA's approach to setting fuel economy standards is to start with automaker product plans, assert that consumers undervalue fuel economy by demanding unrealistic economic returns from fuel saving technologies and assume that automakers are severely constrained in their ability to incorporate new fuel-saving technology into the vehicle fleet. Neither the product plans, nor the assumptions about consumer and automaker behavior relied on in NHTSA's analysis bear any relationship to reality.

- Consumers are looking for higher mileage in the new vehicles today than NHTSA has mandated for seven years from now.
- The product plans on which NHTSA based its rule seven years into the future have already been torn up by the automakers who have belatedly recognized the strong shift in consumer behavior.
- The mix of cars and trucks that NHTSA projects bears no relationship to the vehicles that consumers are buying.
- Not only did NHTSA assume that consumers are unwilling to buy fuel economy beyond a very narrow economic assumption, but it also assumed that higher fuel economy has no value in the marketplace (particularly in resale value), which is contrary to what is happening in the market.

Our market behavior analysis and public opinion polling show that consumers want more fuel-efficient cars than the automakers are offering them. The crucial role of a higher fuel economy standard is to push the automakers to deliver what the public wants and deliver the maximum feasible fuel economy, but NHTSA has failed to do so.

The second problem in the Draft Environmental Impact Statement stems from the fact that NHTSA takes a fundamentally flawed approach to its externality analysis. This was evident in the analysis of the military and strategic externalities in the proposed rule, where NHTSA engaged in reasoning that can, at best, be described as blind incrementalism.

- Rather than see improvements in fuel economy as a part of a broader solution to the national oil addiction, NHTSA argues that because this rule alone cannot solve the problem, it does not deserve to be counted as making a contribution to the solution.

- Implementing a law entitled the Energy Independence and Security Act, NHTSA concluded that oil consumption has no military or strategic value whatsoever.

The analysis of environmental impacts suffers from the same affliction. Because improvements in fuel economy alone do not solve the climate change problem, they are shown to have zero effect on the damage that global warming will do. Yet, every reasonable analysis of the big picture and the global impacts of greenhouse gas emissions recognizes that reductions of emissions in the transportation sector must play a large role in the overall solution to the problem.[2]

- Indeed, because of the nature of the sector, it is vital to get the maximum possible contribution to reductions from this sector to achieve a solution.
- Because no individual policy can solve the problem, this approach will reject every policy measure individually, even though taken together they can actually solve the problem.

Unfortunately, in NHTSA's approach, the whole is not even equal to the sum of its parts. NHTSA's approach embodies a myopic bias against action. NHTSA should start from an estimate of what the value of a solution to the national energy problem would be worth, and then give increases in fuel economy credit for their role in that solution.

The Draft Environmental Impact Statement is essentially meaningless because the underlying analysis is so fundamentally flawed that the agency has not considered an appropriate range of policy options for which the environmental impact should be evaluated, and the environmental impacts are not set in the proper context of the problem that needs to be addressed. The challenge of national security and environmental impact that emanates

---

[2] Raymond Kopp and William A. Pizer, *Assessing U.S. Climate Policy Options* (Resources for the Future: November 2007), estimate that the transportation sector is the second largest source of greenhouse gas emissions and "vehicle use alone accounts for roughly 16 percent of total U.S. emissions and that emissions from this sector have been growing fifty percent faster than the economy-wide rate of growth of emissions (pp. 24, 162). Moreover, McKinsey and Company and The Conference Board, *Reducing U.S. Greenhouse Gas Emissions: How Much at What Cost?* (December 2007), shows vehicle fuel economy as one of the lowest costs options for reducing greenhouse gas emissions

from the nation's addiction to oil are global and multifaceted, and the analytic framework must recognize that fuel economy standards are one important part of a broader solution.

NHTSA'S PROPOSED RULE DOES NOT REFLECT THE AUTO MARKET REALITY

The attached study of consumer attitudes and auto market behavior prepared by the Consumer Federation of America has a series of findings that call into question the fundamental approach that NHTSA took to set the standard and compel NHTSA to thoroughly reconfigure its analytic approach before it issues a final rule.

Consumers are deeply concerned about rising gasoline costs and the national security implications of our dependence on foreign oil and are prepared to take actions to remedy these problems. Neither the auto industry in its marketing plans nor NHTSA in its proposed rule has fully comprehended the current state of consumer attitudes toward fuel efficiency and the state of the auto market.

- Eighty-four percent of respondents say they are concerned about rising gasoline prices (70 percent very concerned) and eighty-four percent say this rise in price has placed a financial burden on their household budgets (63 percent say severe).
- Seventy-four percent of respondents say they are concerned about Mid Eastern oil imports (57 percent very concerned).
- Among those who drive and intend to purchase a vehicle, the current average fuel economy of their vehicle is reported at about 24.1 mpg, but they intend to get 32.7 mpg in their next vehicle.
- Thus, the average goal for consumers in the market <u>today</u> is 32.7 mpg above the standard of 31. 6 mpg that NHTSA has set for 2015.
- There is a huge mismatch between consumer demand and models offered by automakers in 2008. Whereas 59 percent of the respondents say they want to get more than 35 mpg in their next vehicle, only 1 percent of the models offered by automakers in the first half of 2008 achieve that mileage.

- About 60 percent of the poll respondents say they are willing to consider major changes to achieve higher fuel economy, including switching to four cylinder engines, small cars and hybrids.

Moreover, as the attached report shows, consumers are not merely considering these measures to achieve higher fuel economy; they are acting on their attitudes.

- Four cylinder engines have increased their market share dramatically.
- Smaller cars are in exceptionally high demand, while trucks and SUVs languish on the lots.
- Hybrids are flying out of the show rooms.

However, in direct contradiction to these market trends, NHTSA's proposed rule restricts the level of the standard because it makes assumptions about consumer behavior or automaker ability to incorporate fuel-saving technology that fail to reflect this market reality. NHTSA refuses to consider vehicle downsizing or different performance characteristics as a means of increasing fuel efficiency. NHTSA's underlying assumptions are so out of touch with reality that they are arbitrary and capricious, resulting in a rule that is unreasonable.

The change in consumer attitudes and purchasing patterns has deeply affected the resale value of vehicles, yet NHTSA's proposed rule does not recognize the impact of fuel economy on the resale value of vehicles. NHTSA erroneously assumes that a gas guzzling SUV has the same resale value (as a percentage of the original purchase price) as a fuel sipping small car.

- Contrary to this assumption, SUVS and pickups are piling up on dealer lots across the country.
- SUVs and trucks, both new and used, have plummeted in value, while small cars have increased sharply.
- The Big 3 U.S. automakers announced plans to discontinue leasing these vehicles precisely because the value at the end of a lease is so much lower than the price they have to pay.

The faulty assumptions on resale value play a critical role in NHTSA's analysis by undervaluing fuel efficiency in its consumer payback analysis and preventing NHTSA from including more fuel savings in the fleet in its evaluation of standards.

The analysis of auto market behavior in the attached report shows that these consumer attitudes and trends were not a sudden development in the early part of 2008. They have been evident and progressing for several years. The auto industry and NHTSA have simply ignored the clear evidence.

- The shift in sales was not sudden, nor is it only the result of a shift from trucks to cars. Consumers have also been demanding greater fuel economy within vehicle categories.
- The structural shift to fuel economy occurred in 2004 for trucks and 2006 for cars.
- The effect has built over time so that by the first half of 2008, the level of fuel economy of a car model accounts for over 40 percent of the variance in the change in sales.
- Simply put, it did not take $4/gallon gas to cause the change in consumer behavior, it started at least three years ago when gas was $2.50 per gallon and has been growing progressively.

The automakers not only missed the shift in consumer behavior, they actually tried to resist it by continuing to pump out gas-guzzlers and trying to bribe consumers to buy them with rebates and low interest. However, the trend has proven too powerful and fundamental to resist. Now that the automakers have recognized that they must change, they are rapidly shifting their operations, retooling plants and adopting new technologies at a pace that is far greater than NHTSA had assumed possible. Thus, NHTSA's auto market model erroneously assumes a slow incorporation of fuel savings technology into the vehicle fleet for several reasons. Not only were the product plans on which NHTSA based its proposed rule thoroughly outdated, but also the ability of automakers to change was vastly underestimated by NHTSA. A rule based on data that is so out of touch with reality is arbitrary and capricious and unreasonable.

THE FLAWS IN THE ANALYTIC FRAMEWORK

The failure of NHTSA's proposed rule to reflect the auto market reality is magnified by an analytic structure and economic assumptions that are equally flawed. As described in earlier comments in this proceeding, **NHTSA has inexplicably undervalued the benefits of increased vehicle fuel economy**. In its economic assumptions, NHTSA has chosen to grossly undervalue gasoline consumption and therefore undervalues the fuel savings that will flow from a higher fuel economy standard. To arrive at the proposed rule, NHTSA:

- Used gasoline prices that are far too low – a price of only $2.45 per gallon for 2015 (in 2008 dollars);
- Discounted the value of fuel savings at an unnecessarily high rate; i.e. after identifying two possible discount rates: 1) a high rate based on the automaker view of capital costs and 2) a low rate based on the consumer view of consumption expenditures. NHTSA failed to choose a rate between the two, instead applying the high "capital" rate.
- Assumed that consumers irrationally burn up their fuel savings on increased driving, rather than using it to buy other goods and services, and applied this excessive "rebound" effect to analyses where it should not play a role.

Combined, these overt flaws in NHTSA's economic assumptions have led the Administration to value gasoline savings at less than half of what would be a reasonable estimate.

NHTSA failed to give the "need to conserve energy" proper consideration in light of the clear, obvious, and painful national energy crisis currently facing all Americans In speaking for the American public, Congress was very clear in its requirement that NHTSA set the fuel economy standard at the "maximum feasible level." In doing so, NHTSA was to take into consideration "the four statutory factors underlying maximum feasibility (technological feasibility, economic practicability, the effect of other standards on fuel economy, and the need of the nation to conserve energy)." NHTSA completely failed to give proper consideration to this last and most fundamental reason for the Act: "the need of the nation to conserve energy."

In its analysis, NHTSA identified two alternatives that bracket the range of possibilities that are economically practicable. One alternative – the "total benefit equals total cost (TB=TC)" alternative would maximize fuel savings at no net cost to society, by including fuel savings technologies until the total cost equals the total benefit. The other economic extreme, which HNTSA called the "optimized" approach, would maximize the economic return of investments in fuel economy by including fuel savings technology only up to the point where marginal benefits equal marginal costs.

- We believe that the TB=TC approach is the proper way to recognize "the need of the nation to conserve energy.
- At a minimum, an approach that would reasonably consider "the need to conserve energy" would balance the economic and conservation concerns and set the standard between the two extremes.
- NHTSA did not do so. It simply chose to set the standard at the lower level with no consideration of the enormous energy conservation cost of that decision.

NHTSA chose to define "feasibility" and "practicability" in a manner that lets the least fuel-efficient automakers drive down the standard. It protects the least capable automakers rather than requiring them to rise up to the level that the industry as a whole could achieve. Ironically, by setting a lower standard, in the face of dramatically rising consumer expectations, the Administration is creating an environment of failure for those companies who are driving down the standard. NHTSA allows the laggards in the industry, who have been trailing farthest behind the shift in consumer behavior, to pull the standard down.

NHTSA SET UNREASONABLY LOW STANDARDS FOR AN UNREASONABLY LONG PERIOD

Throughout its analysis, NHTSA indicates that certain assumptions were made with incomplete data and without critically important information about the auto market. Nevertheless, for no apparent reason, NHTSA set this low standard for the maximum period allowable under the law. NHTSA excuses the failure to obtain complete and accurate data for its assumptions with a claim that it must promulgate a standard for model year 2011 by mid-2009 in order to give automakers proper advanced notice. While that is correct, **there was no need to rush to promulgate standards for later model years, certainly not 2013 through 2015.** With numerous important issues still under study, it was incredibly irresponsible for NHTSA to write rules for years that do not require an expedited process, when additional time would afford a much more informed rulemaking. Critical information missing from NHTSA's analysis includes:

- The effectiveness of available technologies for improving fuel economy;
- The cost of technologies for improving fuel economy;
- Market shares of various models in the vehicle fleet; and
- The value of reduced emissions of greenhouse gases.

Unbelievably, NHTSA fully recognized that it did not have reliable and accurate information in these areas and would obtain that information only after the rule was promulgated. Additional and critical information missing from the Administration's analysis resulted in NHTSA making projections that were way ahead of the data available to them. This is, however, data that could be obtained, which would provide a much firmer basis for developing a rule that applies to 2013 vehicles and beyond. Without this critical data, NHTSA's conclusions:

- Relied on old sales data and projections in a time of rapid change in the industry;
- Failed to consider the impact of vehicle mix on safety;
- Did not incorporate technology adoption strategies ("pull ahead") that speed penetration of fuel-saving technology into the vehicle fleet;
- Ignored recent changes in fuel economy and the practices of automakers in adopting fuel economy technologies; and
- Overlooked changes in vehicle usage patterns across time.

Some underlying data used by NHTSA is suspect and would benefit greatly from even a small amount of further research and disclosure by the automakers, including:

- The production plans of automakers;
- Market share and price data;
- The validity of the speed of adoption of technology (phase-in caps) in light of dramatic changes in auto market behavior; and
- Assumptions about the compliance strategies of auto manufacturers.

There is no question that NHTSA needed to get the rulemaking started for 2011, and perhaps 2012, so it could complete the process eighteen months before the model year, as mandated by the new statute, but going beyond that, in light of the incredible importance of this regulation and the woeful lack of knowledge of critical aspects of the analysis, was irresponsible. NHTSA certainly could have moved forward with this rulemaking in light of these uncertainties by providing the minimum notice necessary, thereby keeping its options open for writing fuel economy standards for later years based on better information.

By rushing ahead with imperfect knowledge, faulty assumptions and a bias against fuel savings, NHTSA's approach denies the critical benefits of reduced gasoline and oil consumption to individual consumers and the nation as a whole. Therefore, it was unreasonable for NHTSA to set standards that run so far ahead of its knowledge. Adopting proposed standards for 2013 to 2015 based on such faulty data is arbitrary and capricious and leads to standards that are unreasonable.

The damage of NHTSA's proposed rule goes beyond the immediate impact of lost savings. By relying on a flawed analytic framework and flawed empirical specifications, this rulemaking undermines future rulemakings in two ways.

- First, procedurally, once this framework is set, it will be difficult to change. Inertia and judicial deference make it difficult to reverse agency decisions.
- Second, setting a low standard makes it far more difficult for the industry to meet higher future standards. Requiring large jumps in improvements is always more expensive than gradual improvements toward a goal, so fixing the mistakes later is harder because the industry is farther behind.

Because of the enormous importance of this particular rulemaking, it is critical for NHTSA to get the fundamental framework correct from the start and to set the standard at a reasonable and achievable level.

RECOMMENDATIONS

Based on our review of the proposed rule, it is clear that NHTSA's analysis is riddled with flaws. The result is a set of proposed fuel economy standards for the period 2011-2015 that is unreasonably low, covers a period that is unreasonably long, and is inadequately documented. NHTSA's proposal meets neither the spirit nor the intent of the Energy Independence and Security Act of 2007. Its flawed analysis and failure to obtain the data necessary to promulgate a reasonable rule violates the Administrative Procedures Act.

Due to the extraordinary urgency needed to respond to the current energy crisis, we recommend the following:

1. NHTSA should explicitly correct the conceptual flaws in its model and establish clear tests and analytic approaches to evaluate standards, independent of the level at which they are set in any given proceeding. NHTSA needs to distinguish more precisely between the "ruler" by which standards will be measured and the "rule," which prescribes the standard at a given moment in time.
2. NHTSA should set the standards for 2011-2012 at a level substantially higher than it has proposed. It should set the standard for 2011 according to the total benefit equals total costs level – 30.6 mpg not 27.8.
3. NHTSA should rescind the standards for 2013-2015, complete the gathering of the critical information that is needed to make an informed recommendation, and develop recommendations based on that information.

These reasonable suggestions, which have been incorporated into detailed comments and submitted to NHTSA on its proposed fuel economy standards, will enable NHTSA to meet its statutory requirements in the short run and do the best possible job of securing America's energy future in the long run. It will also bring NHTSA into compliance with the Energy Independence and Security Act of 2007. This is an extraordinary opportunity to dramatically set our country on the right course toward much needed and long overdue improvements in fuel economy. We trust that the points we have made are compelling and that the Administration will do what is in the country's best interest and adopt our recommendations.

FUEL ECONOMY AND AUTO SALES: AUTOMAKERS AND THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION IGNORE MARKET SIGNALS

MARK COOPER

AUGUST 2008

EXECUTIVE SUMMARY

This analysis explores important and fundamental flaws in the underlying economic assumptions made by the National Highway Traffic Safety Administration (NHTSA) in proposing its 2011-2015 fuel economy standards for autos and light trucks that render the draft environmental impact statement (DEIS) insufficient. NHTSA's proposed fleet wide standards that reach a mere 31.7 miles per gallon in 2015 and are grossly inadequate, robbing consumers and the nation of multiple billions of gallons of vital gasoline savings over the next decade. As a result, the DEIS measures the wrong alternatives and reaches the wrong conclusions about environmental impacts.

NHTSA's approach to setting fuel economy standards is

- to start with automaker product plans,
- assert that consumers undervalue fuel economy by demanding unrealistic economic returns from fuel saving technologies and
- assume that automakers are severely constrained in their ability to apply new fuel saving technology.

Neither the product plans nor the assumptions about consumer and automaker behavior relied on in NHTSA's analysis bear any relationship to auto market reality.

- Consumers are looking for higher mileage today than NHTSA has mandated for seven years from now.
- The product plans on which NHTSA based its rule seven years in the future have already been torn up by the automakers, who have belatedly recognized the shift in consumer behavior toward greater fuel economy.
- The mix of cars and trucks that NHTSA projects bears no relationship to the vehicles that consumers are buying.

Relying on auto industry judgment in product plans, which are out of touch with the market reality, NHTSA has proposed fuel economy standards that are far too low. Not only did NHTSA assume that consumers are unwilling to buy fuel economy beyond a very narrow economic assumption, but it also assumed that higher fuel economy has no value in the marketplace (particularly in resale value). Our market behavior analysis and public opinion polling shows that consumers want more fuel-efficient cars than the automakers are offering them. The crucial role of a higher fuel economy standard is to push the automakers to deliver what the public wants, but NHTSA has failed to do so.

CFA made many of these points in its July comments filed in the rulemaking, but recent events have made the flaws in NHTSA's analysis and framework so much more obvious that we feel obliged to restate our objections to the proposed rule and incorporate new evidence into the record. Our earlier recommendations are all the more compelling in light of the mounting evidence that NHTSA has failed to propose a reasonable standard. NHTSA must:

- Raise the standards for 2011 and 2012; and
- Withdraw the proposed standards for 2013 through 2015, so it can fix its analytical framework and economic assumptions before promulgating fuel standards for those distant years.

The anecdotal evidence of the dramatic changes in the auto market is everywhere. In the past month, the Big Three have announced (or leaked) plans to abandon or slash their leasing businesses because the value of their gas-guzzlers at the end of the lease term is so low that the economics of leasing no longer makes sense. Clearly, fuel economy is a key determinant of the resale value, but NHTSA's analysis assumes that fuel economy has no impact on resale value of vehicles whatsoever.

While data on auto sales for the first half of 2008 make it clear that consumers are highly sensitive to fuel economy in their purchase decisions, our analysis shows that this shift in consumer behavior has been evident for three years. In addition, our analysis reveals that it is not just a shift between trucks (SUVs) and cars, but that it is has also been evident within the car and truck categories.

The automakers were slow to recognize this market change. They chose to continue to produce gas-guzzlers, trying to bribe consumers to purchase them with discounts, rebates and low interest financing. It was a fool's game, and the jig is up. In the past month, the big 3 U.S. automakers have declared their intention to dramatically alter its vehicle mix in the next few years, yet NHTSA assumes that automakers cannot make such changes rapidly. Assuming that vehicle manufacturers are unable to make such changes causes NHTSA to severely underestimate the fuel savings technologies that could be included in new vehicles. Pushing automakers to close the gap is precisely the role of fuel economy standards. The technologies exist to achieve almost twice the fuel savings that NHTSA's proposed rule achieve, but NHTSA has incorrectly assumed that consumers lack the desire and automakers lack the ability to get these technologies into the fleet.

Dramatic changes in the marketplace reflect a greater willingness of consumers to buy more fuel-efficient vehicles (new and used). However, at the core of NHTSA's analysis are assumptions that restrict the inclusion fuel saving technologies in new vehicles. NHTSA's base case fuel economy levels and vehicle mix simply do not reflect the reality of the auto market. Our survey evidence analyzed below demonstrates the motivation and willingness of consumers to purchase more fuel-efficient vehicles and reveals a shocking mismatch between what consumers want and what automakers have been offering.

The remainder of this report examines the increasing responsiveness of the auto market to fuel economy, which was not fully reflected in NHTSA's modeling. NHTSA has based its proposed rule on automaker product plans that are completely outdated. It did not have to set standards beyond 2012 in the current rulemaking and the choice to do so, despite clear evidence that the product plans do not reflect reality, violates the letter and spirit of the Energy Policy Conservation Act (EPCA) as recently amended by the Energy Independence and Security Act of 2007. Instead of proposing rules that achieve the maximum feasible increases in fuel economy, as obligated under the EPCA, NHTSA has proposed rules that are much closer to the minimum allowable.

In our initial comments we demonstrated that if NHTSA repaired the analytic framework and corrected its economic assumptions, it could easily go to a much higher standard that would push the fleet average for 2015 from 31.6 mpg to 34.5 mpg. Given the dynamic developments in the marketplace, NHTSA should certainly consider even higher levels for 2013 to 2015. The highest level of fuel economy that NHTSA considered, called the "technology exhaustion" standard, was based on erroneous assumptions about the inability of automakers to improve fuel economy. The technology exhaustion alternative, which would move the fleet to 41.4 mpg by 2015, is certainly technologically feasible and, under realistic assumptions about the value of oil and externalities, would not only save 50 billion gallons more gasoline, but also produce $30 billion more in net total benefits. With so much potential gain for consumers and the nation, NHTSA must adopt a more realistic model of consumer and automaker behavior, adjust the economic assumption and consider much higher levels of fuel economy.

This report is divided into three sections:

- Consumer Attitudes
- Fuel Economy and Year-Over-Year Changes in Auto Sales
- Changes in Consumer Behavior in Gasoline and Auto Markets

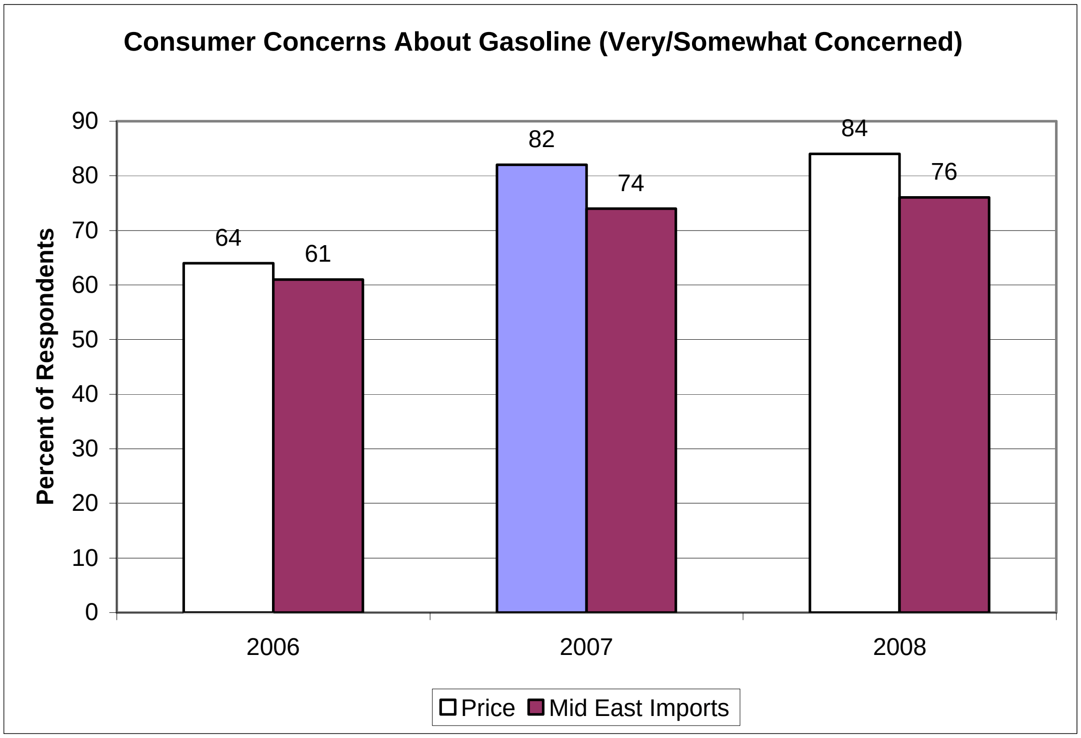
The next section presents a discussion of recent survey evidence on the shift in consumer and market behavior, which must inform NHTSA's analysis. We then analyze year-over-year changes in sales and fuel economy to ascertain when the shift in consumer behavior occurred. Finally, we review long run trends and present an econometric analysis of fuel economy over the past half-decade.

CONSUMER ATTITUDES

Our survey evidence demonstrates the motivation and willingness of consumers to purchase more fuel-efficient vehicles (see Exhibit 1).

- Eighty-four percent of respondents say they are concerned about rising gasoline prices (70 percent very concerned).[1]
- Seventy- six percent of respondents says they are concerned about Mid Eastern oil imports (57 percent very concerned).
- Both of these figures have been rising steadily since we began asking the question about two years ago.

Exhibit 1:



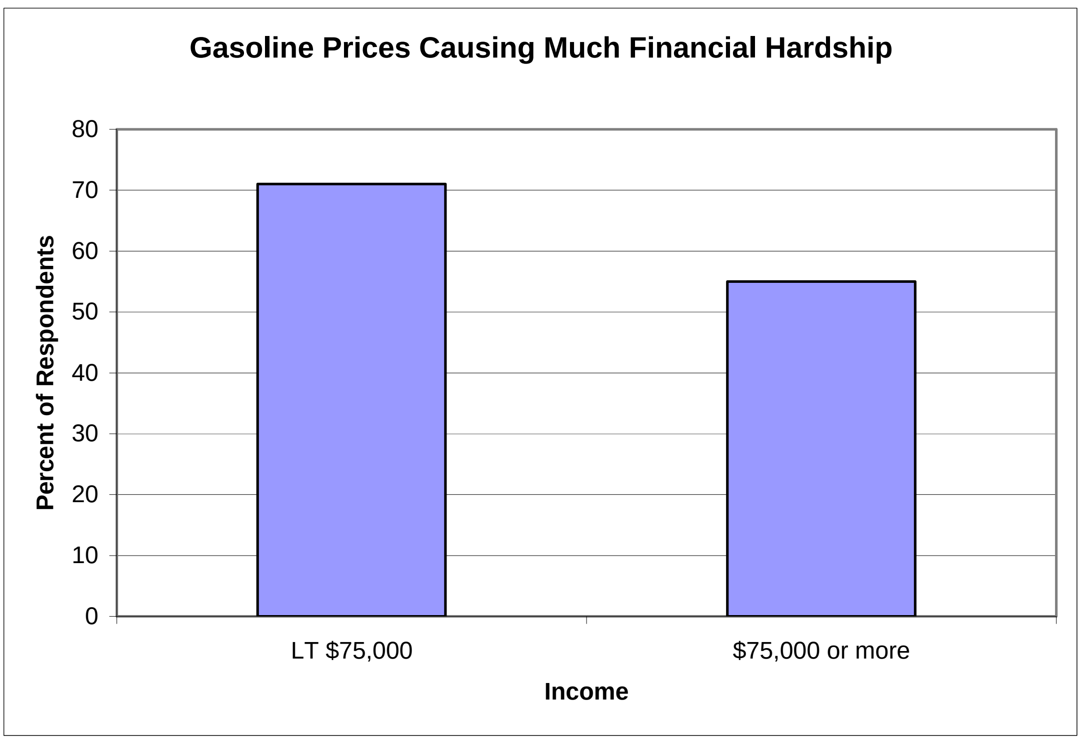
Source: National opinion polls conducted for the Consumer Federation of America by the Opinion Research Corporation. 2008, July 17-20; 2007, see Consumer Federation of America, *No Time to Waste*, available at http://www.consumerfed.org/pdfs/No_Time_To_Waste.pdf 2006 see Consumer Federation of America, *Consumers Still Greatly Concerned About Better Gas Mileage and Oil Imports Despite Falling Gas Prices, available at http://www.consumerfed.org/pdfs/Gas_Mileage_Consumer_Attitudes_Manu_Performance_Press_Release111306.pdf*

[1] "Thinking about the next five years, how concerned personally are you about gasoline prices, U.S. dependency on Mid Eastern oil, and global warming?"

There are no significant differences in these concerns across various demographic categories (age, income, education, gender) with one exception. Households with incomes of $35,000 per year or more are more likely to be concerned about Mid East imports (81 percent) than those with incomes below $35,000 (69 percent).

The concern about gasoline prices reflects the impact that rising gasoline prices are having on the respondents. Eighty-four percent of respondents say that rising gasoline prices have placed a financial burden on their household budgets (63 percent a severe burden). Not surprisingly (see Exhibit 2), households with incomes of $75,000 or more are less likely to say they have suffered much financial hardship (55 percent) than households with incomes below $75,000 (71 percent.) Also, rural households (those living outside of metropolitan areas) are more likely to say they have suffered much financial hardship as a result of gasoline costs (35 percent) compared to those living in urban areas (26 percent).

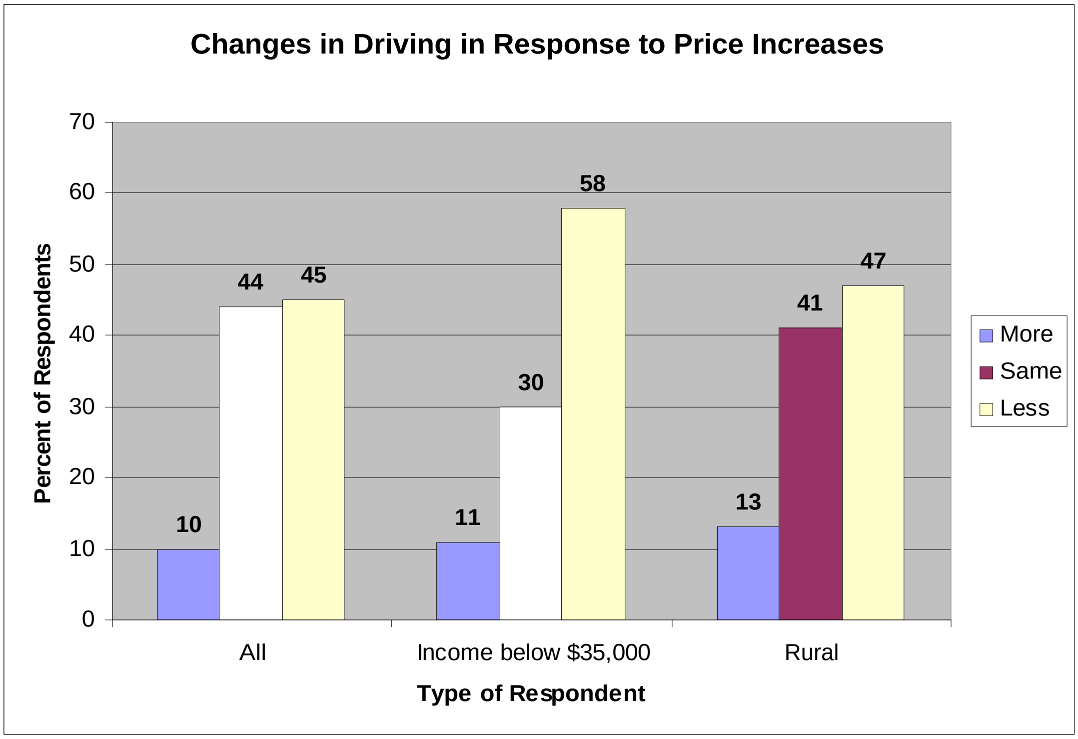
Exhibit 2:



Source: National opinion poll conducted for the Consumer Federation of America by the Opinion Research Corporation. 2008, July 17-20

Our April 2008 survey also helped reveal how Americans are responding to this hardship.[2] When asked (whether they were driving more or less than a year ago, 45 percent of respondents said less, and only 10 percent said more (see Exhibit 3). Lower income households were more likely to say that they were driving less (58 percent compared to 45 percent for all respondents).

Exhibit 3



Source: See Mark Cooper, *Ending America's Oil Addiction* (Washington, D.C.: Consumer Federation of America, April 2008). http://www.consumerfed.org/pdfs/First_Quarterly_Gas_Report_2008.pdf

The most striking result of the most recent survey can be found in responses to questions about the fuel economy of the vehicles consumers currently drive compared to the fuel economy they would like to get in their next vehicles.

- Among those who drive and intend to purchase a new vehicle, the current average fuel economy is reported at about 24.1 miles per gallon.
- These respondents say they want to get 32.7 miles per gallon in the vehicle they purchase.

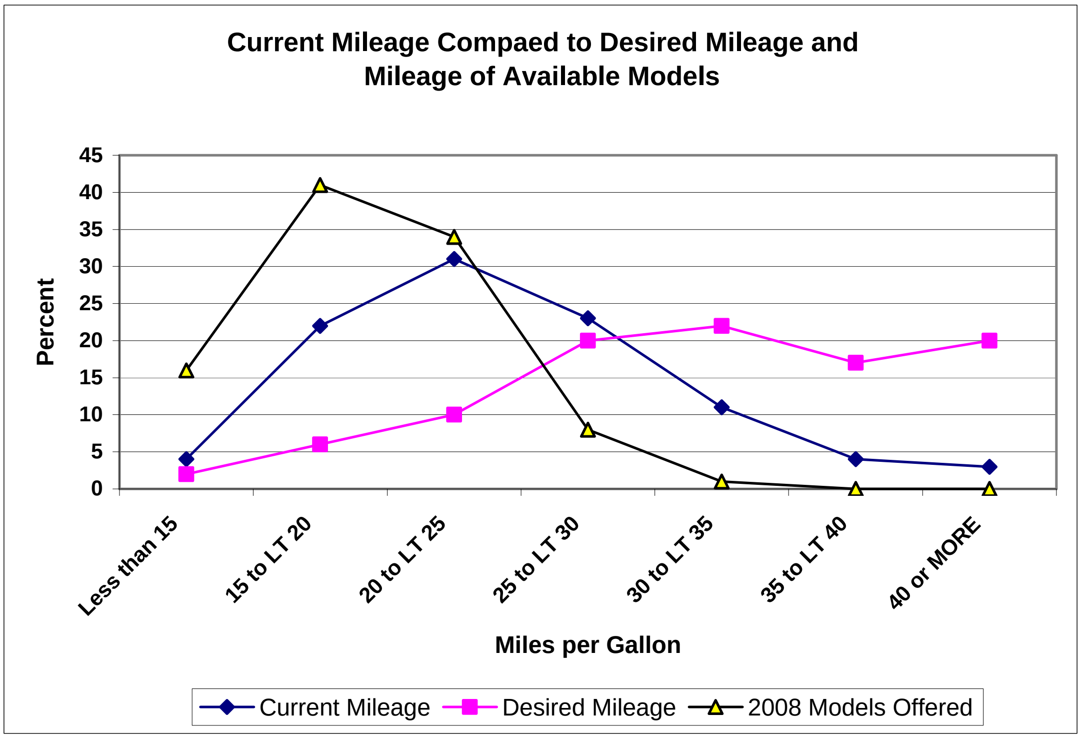
[2] See Mark Cooper, Ending America's Oil Addiction (Washington, D.C.: Consumer Federation of America, April 2008).

http://www.consumerfed.org/pdfs/First_Quarterly_Gas_Report_2008.pdf

There is also a clear mismatch between the desires of consumers and the models that the automakers offered in 2008 (see Exhibit 4).

- Whereas 59 percent of the respondents say they want to get more than 35 miles per gallon in the next vehicle they purchase, only 1 percent of the 2008 models offered by automakers achieve that mileage.
- The average goal for consumers in the market today is 32.7 miles per gallon, well above the standard of 31.6 miles per gallon that NHTSA has set for 2015.

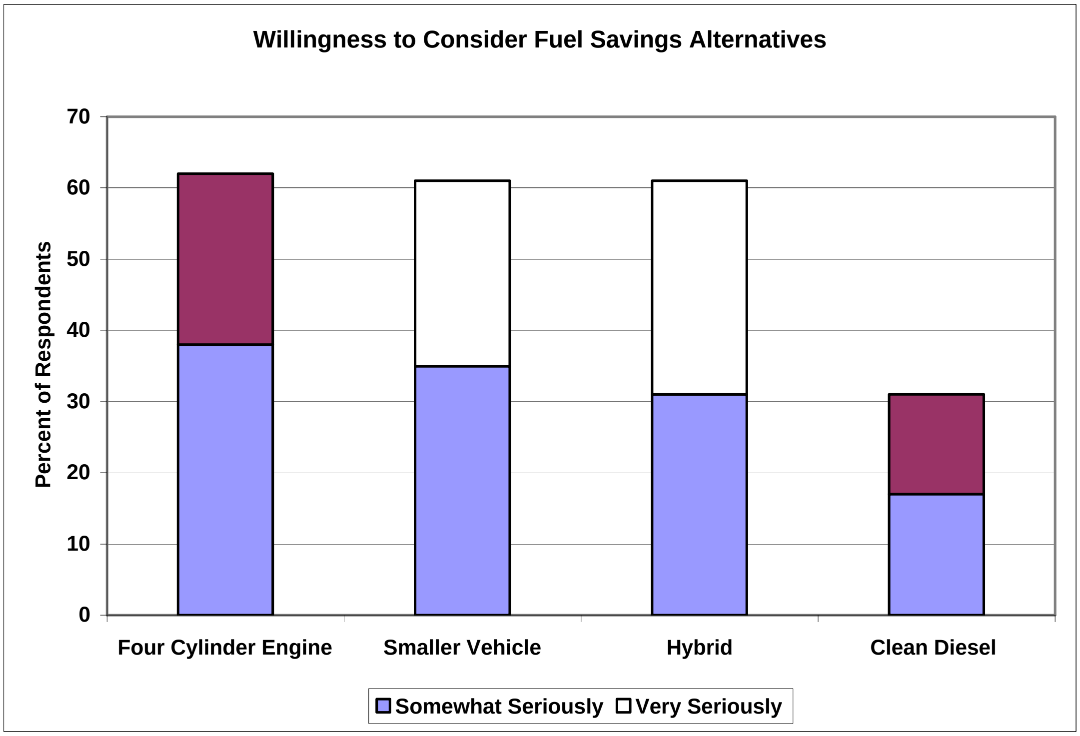
Exhibit 4:



Source: National opinion poll conducted for the Consumer Federation of America by the Opinion Research Corporation. 2008, July 17-20; CFA database on miles per gallon.

Consumers back up their desire to achieve higher fuel economy in their next vehicles with a willingness to consider alternatives that would lower fuel economy (see Exhibit 5.) When asked about four major ways to improve fuel economy, about 60 percent of respondents said they would very or somewhat seriously consider four cylinder engines, hybrids and small vehicles. Clean diesel engines would be considered by about one-third of respondents. There were few differences across demographic categories, with two exceptions. Respondents with incomes above $50,000 were more willing to consider a hybrid (68 percent) than those with incomes below $50,000 (57 percent). Younger (age 18-24) and older respondents (age 65 or more) were less likely (50 percent) to say they would consider a hybrid than respondents with ages between 25 and 65 (70 percent).

Exhibit 5:



Source: National opinion poll conducted for the Consumer Federation of America by the Opinion Research Corporation. 2008, July 17-20;

These attitudes are impacting behavior in the marketplace. Consumers do not just say they are feeling the pinch of rising gasoline prices, or claim to alter their behaviors in reaction to higher gasoline prices, or just express a desire to have more fuel efficient vehicles, the evidence on auto sales suggests that they are taking action. Consumers are switching to smaller vehicles[3] with smaller engines.[4] Large vehicles are piling up on lots and losing value both as new and used vehicles.[5] Automakers are dramatically retooling their production plans in response to consumer behavior.[6]

FUEL ECONOMY AND YEAR-OVER-YEAR CHANGES IN AUTO SALES

While the headlines describing the current woes of the automakers point to a sudden shift in consumer purchasing patterns, a shift from light trucks and large SUVs to more fuel-efficient cars, a close look at the data indicates that:

- There was nothing sudden about the shift.
- It involves much more than a shift from trucks and SUVs to cars (higher fuel economy within vehicle types sells more vehicles).
- Simply put, it did not take $4 gas to cause the change in consumer behavior, it started at least three years ago when gas was $2.50 per gallon and has been growing progressively.

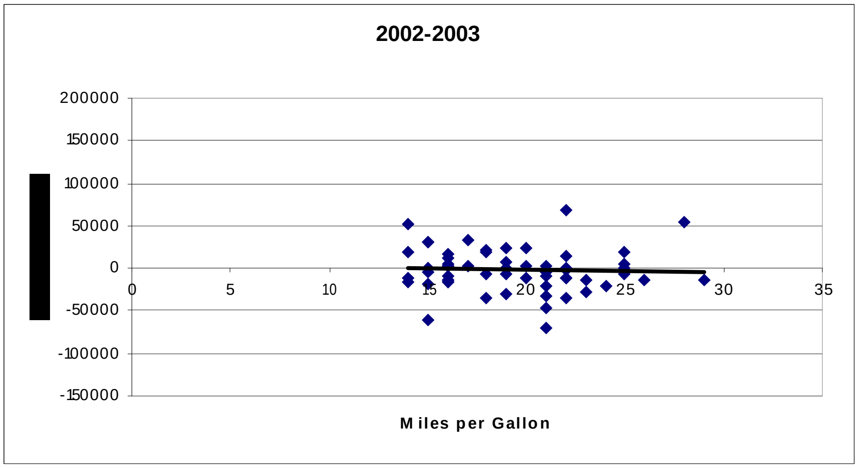
The automakers not only missed the shift in consumer behavior, they actually tried to resist it by continuing to pump out gas-guzzlers and trying to bribe consumers to buy them with rebates and low interest.[7] To examine this issue we compiled a database of the top fifty models in each year and charted their sales (reported by Automotive News) and EPA mileage ratings across time. There is an average of 61 models in each year-to-year comparison (because different models will be included in the top fifty in one year, but not the next). A total of 83 models occurred in the top fifty over this period for which we had sales and mileage data. These models represent an average of approximately two-thirds of all units sold over the period.

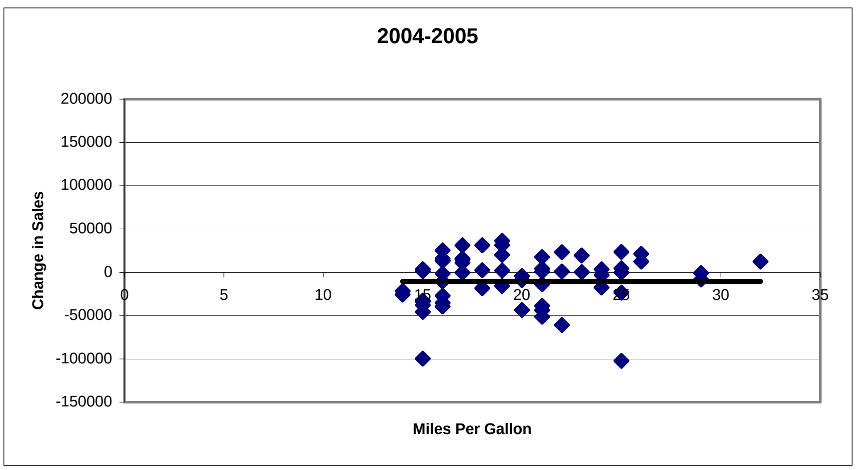
Exhibit 6 shows the sales for the top sixty models, plotting EPA mileage ratings (all based on the new method) against the change in sales. From 2003-2005, there was no relationship between fuel economy and sales; the regression line was flat. Starting with the 2005-2006 comparison, there is a relationship; vehicles that got higher mileage fared better in the marketplace. The relationship persisted in 2006-2007 and through the first half of 2008. While the direction of the relationship remained about the same (i.e. the slope of the line did not change much) the relationship became much stronger (the scatter of the observations around the line became smaller in magnitude). In the first half of 2008, the level of fuel economy of the model accounts for over 40 percent of the variance in the change in sales.

The graphs in Exhibit 5 exclude the Prius, which is the only hybrid to be ranked in the top fifty over this period and has been so popular that there have been delivery delays. (It is an outlier and its "poor" performance in recent years is not the result of a lack of demand but, rather, the result of a lack of supply. This is a circumstance that is radically different than that faced by vehicles with conventional engines).

[7] While the discounting practices are obvious, blasted incessantly across TV screens and in newspaper advertising, rigorous analysis is rare. One early analysis (Walter McManus, "The Link Between Gasoline Prices and Vehicle Sales," *Business Economics,* January 2007) shows that the shift in pricing occurred in early 2005.

Exhibit 6: Fuel Economy Affects Changes in Sales





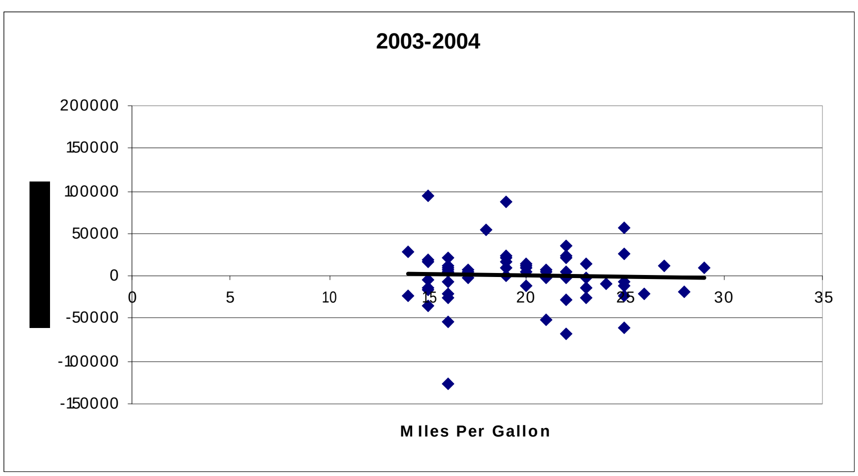


Exhibit 5 (cont'd):

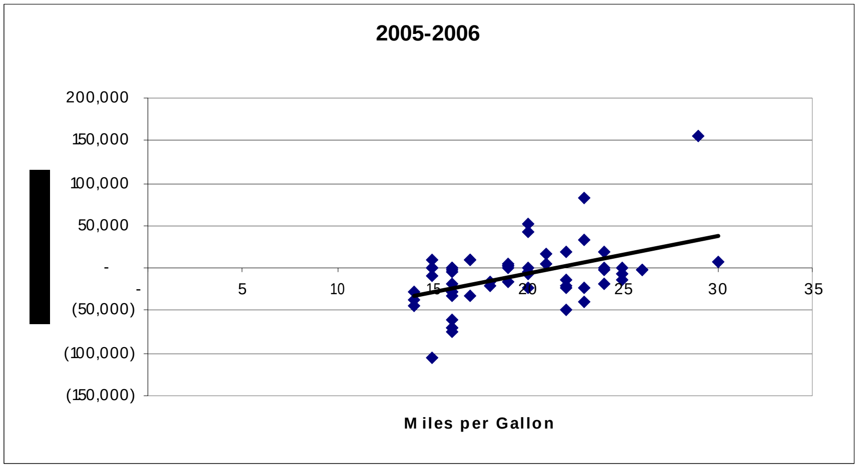
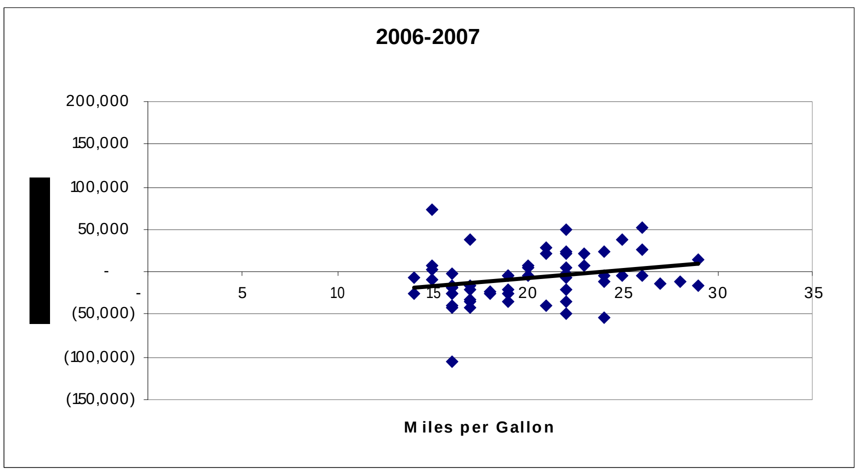
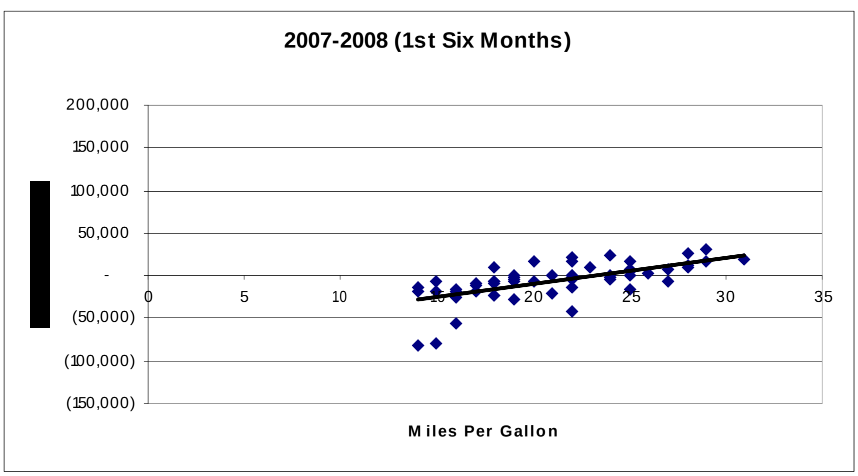


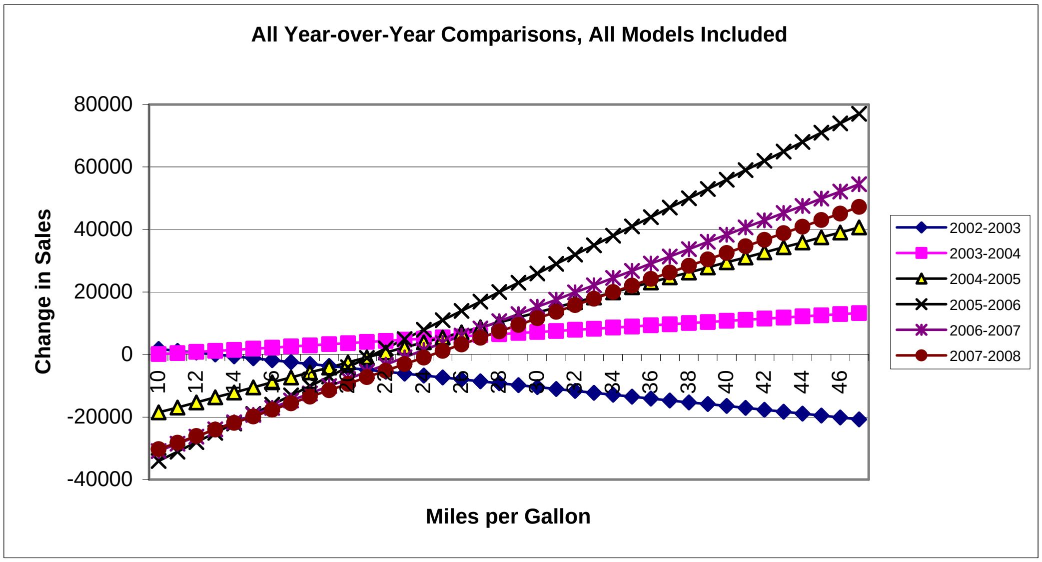


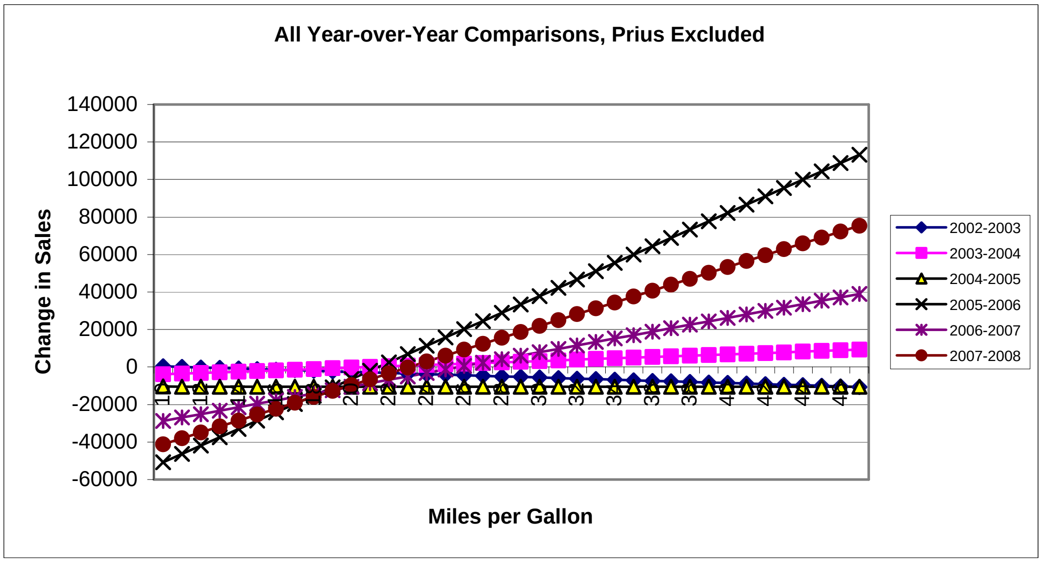


Source: CFA Data Base

Exhibit 7 shows the individual regression lines (without the data points) for all vehicles and vehicles with conventional engines. The graphs show that the shift in the market took place well before the first half of 2008. Including the Prius does not change that conclusion; it merely pushes the data of the market structural change back one year.

Exhibit 7





Source: CFA Data Base

The above analysis concludes that fuel economy played a key part in determining sales in recent years. We explored alternative explanations that might account for the shift in buying patterns. One obvious possibility is a shift in preference away from truck and SUVs. Exhibit 8 shows that the structural shift is not the result of a shift from trucks to cars. We examined this in two ways. In one set of regressions, we introduced trucks as a covariate, to control for the effect of being a truck model as opposed to a car model. Even controlling for the type of vehicle (car v. truck) fuel economy is an important determinant of the change in sales. A second approach is to examine the relationship between fuel economy and sales separately for cars and trucks. Our conclusion that the structural shift occurred well before the first half of 2008 is confirmed and strengthened. The structural shift occurred in 2006 for cars and somewhat earlier (2005) for trucks.

Exhibit 8: Regression Results: Fuel Economy as a Predictor of Sales

Year	All Light Duty Vehicles			All Light Duty Vehicles (Truck Covariate)			Cars Only			Truck Only		
	B	Sig.	R2	B	Sig.	R2	B	Sig.	R2	B	Sig	R2
2002-2003	-297	*	0	1697		3	4511	*	7	-179		0
2003-2004	-354		0	68		0	-624		0	2842		0
2004-2005	-4		0	1036		0	-940		0	4535	**	9
2005-2006	4429	***	21	5463	**	20	3020	*	0	3738		5
2006-2007	1833		2	4487	**	6	4191		6	4878	*	9
2007-2008	3150	***	42	3124	***	41	2752	***	31	3778	**	17

*** $p < .10$, ** $p < .0$,*** $p < .01$**

We also examined the issue of whether the change in mileage for a specific model, year over year, affected change in sales. While all of the coefficients were positive, indicating better mileage was associated with better sales performance, none was statistically significant and all were small. This should not be surprising because the improvement in fuel economy within models was quite small, only 1 mile per gallon, on average, over the five year period from 2002-2005. It is the much larger differences in mileage between models that are having the effect.

CHANGES IN CONSUMER BEHAVIOR IN GASOLINE AND AUTO MARKETS

Thus far we have seen that public opinion and new car sales indicate a clear shift in consumer attitudes toward fuel economy. A recent Congressional Budget Office Study[8] (CBO) explores similar issues and reinforces our findings. What are the effects of high prices on consumption patterns? After four years of rising prices (2002-06), CBO found that when gasoline prices rise significantly, people will:

- Use less gasoline;
- Drive less if they can;
- Drive more slowly;
- Use mass transit where it is available; and
- Buy more fuel-efficient cars, if they can find them.

The formal expression of this relationship in economic analysis is the price elasticity of demand. How much does a particular behavior change in response to a price change? The price elasticity of demand is usually calculated in percentages. A one-percentage point increase in prices that results in a one-percentage decline in the behavior is said to be an elasticity of -1 (-.01/+.01 = -1). CBO studied a variety of behaviors and calculated the elasticity of demand – the percentage change in a particular behavior in response to a change in gasoline prices. As Exhibit 9 shows, there is a small, negative price elasticity. The short-run elasticities are considerably less than -.1. A one percent increase in price leads to a reduction in consumption or changes in behavior that reduce consumption of less than one-tenth of one percent. In the long run, the elasticities are somewhat higher -.2 to -.4, but still quite low compared to other commodities. Moreover, the elasticity of demand has declined over time and is likely to continue to do so.

> For a variety of reasons, consumers are currently only about one-fifth as responsive to short-run changes in gasoline prices as they were several decades ago. That decline in sensitivity has been attributed to growth in real income, which has rendered gasoline a smaller share of consumers' purchases from disposable income. Price sensitivity has also declined because a gallon of gasoline takes a car farther than it did in the past, in part because of fuel economy standards. The development of distant suburbs also has contributed by making consumers more reliant on the automobile. The longer commutes are balanced by lower housing costs.[9]

b) Jon B. Taylor, *Economics* (Boston: Houghton Mifflin, 1998), *p*. 99.

To track the trends in vehicle fuel economy, the CBO relied on Environmental Protection Agency (EPA) mileage estimates and auto sales from *Automotive News.* CFA compiled a database on fuel economy and sales using NHTSA data.[10] Our analysis includes more recent data than was used by the CBO, allowing us to extend some analyses to 2007 with preliminary sales data. We find similar patterns of shifts to more fuel-efficient vehicles in consumer purchasing behavior, and with these data,

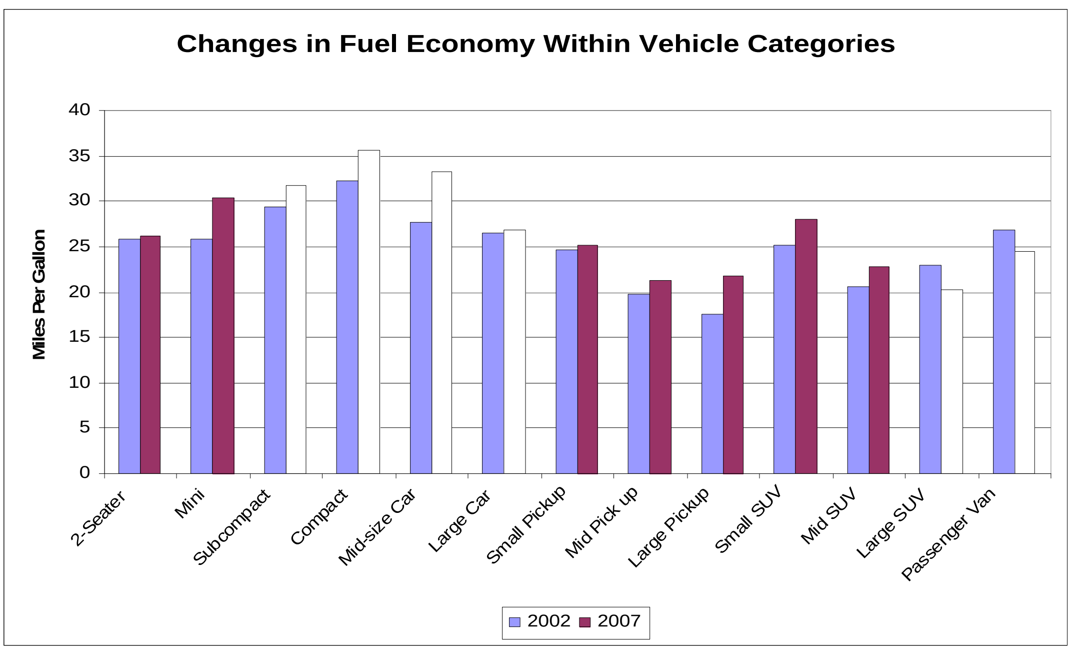
[10] Jack Gillis and Mark Cooper, *Still Stuck in Neutral: America's Continued Failure to Improve Motor Vehicle Fuel Efficiency: 1996:2005*, July, 2007, available at http://www.consumerfed.org/pdfs/Still_Stuck.pdf; Jack Gillis, Stuck *in Neutral: America's Failure to Improve Motor Vehicle Fuel Efficiency: 1996-2005*, November 2006; available at http://www.consumerfed.org/pdfs/Stuck_in_Neutral.pdf.

we can explore some important aspects of the automotive market in greater detail.

As gasoline prices rise, people switch from less fuel-efficient trucks to cars. As the CBO noted, "Price spikes in the spring of 2005, in October 2005 (after Hurricane Katrina), and in the spring of 2006 all coincided with sharp increases in the new-car market share. Market shares for leading categories of light trucks – especially SUVs – went the opposite way, dipping as gasoline prices rose."[11] In our data, with annual sales, the shift is 2.3 percent. Applying the shift coefficient calculated by CBO to the average difference between cars and trucks in our data, we find that the switch results in an improvement of fuel economy of about .1 percent for every 1 percent increase in gasoline prices. We arrive at a similar estimate by calculating the change in the fleet average fuel economy compared to the average real price of gasoline.

One of the key findings of the CBO study is that fuel economy improved both because consumers shifted their purchases away from less fuel-efficient types of vehicles (trucks and large SUVs) and because "the average fuel economy of cars and light trucks alike have been increasing since 2002."[12] Our data shows (see Exhibit 10)

Exhibit 10:



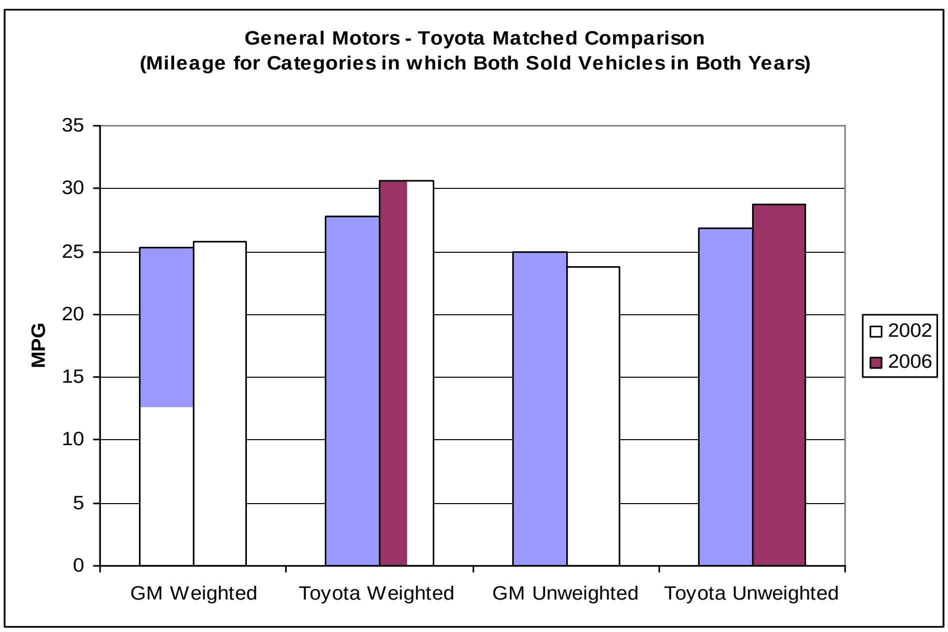
Source: Mark Cooper, *Ending America's Oil Addiction* (Washington, D.C.: Consumer Federation of America, April 2008).
http://www.consumerfed.org/pdfs/First_Quarterly_Gas_Report_2008.pdf

[11] CBO, Effects of Gasoline Prices, p. 16.
[12] CBO, Effects of Gasoline Prices, p. 20.

that the overall improvement in fuel economy was just under one mile per gallon (for 2002-2006) and 2 miles per gallon for 2002-2007; much less than consumers now say they want (8 mpg). And, the improvement in the fuel economy within the individual categories of cars and light trucks is uneven. The largest improvements came in minis, compacts, and mid-sized cars. Passenger vans and large SUVs did not improve much (which is why sales plummeted). While many consumers shifted to smaller more fuel-efficient vehicles, those who required larger vehicles could not find the fuel-efficiency they needed and wanted.

Fuel economy improvement was also very uneven across auto manufacturers. One of the more dramatic aspects of the past half-decade has been the competition between General Motors (GM) and Toyota for the top spot as the leader in sales in the American auto market. The following figure shows the average fuel economy for GM and Toyota based only on categories of cars in which both had sales in 2002 and 2007 (see Exhibit 11). This graph matches the two automakers by categories of product sold for which they compete head-to-head. It shows both the sales-weighted average fuel economy (mpg) and the unweighted average of the individual models they marketed. For Toyota, both the weighted and unweighted fuel economy averages improved. Toyota's mileage improved both because consumers shifted their purchases to more fuel-efficient categories of vehicles and Toyota offered, on average, significantly more fuel-efficient models. GM's average fuel economy improved because consumers shifted their sales between categories, but GM did not offer, on average, a significantly more fuel-efficient slate of models.

Exhibit 11:



Source: Mark Cooper, *Ending America's Oil Addiction* (Washington, D.C.: Consumer Federation of America, April 2008). http://www.consumerfed.org/pdfs/First_Quarterly_Gas_Report_2008.pdf

We were able to test the proposition that fuel economy became more important to consumers over the period since 2002 with an econometric model of fuel economy (see Exhibit 12). After controlling for the key vehicle characteristics that affect fuel economy (vehicle weight, engine traits like horsepower, displacement, number of cylinders, transmission type, drive ratio, dynamometer setting, wheel base, interior volume), each year after 2002, there was a statistically significant, though small, improvement in the fuel economy of cars. For cars, the effect became steadily larger over time. A car sold in 2006 got 2.377 more miles per gallon than one built in 2002, controlling for all the other factors included; for trucks, the increase was .879 miles per gallon.

Exhibit 12: Linear Regressions to Examine Factors Affecting Fuel Economy
(Unit of Analysis is the Sales Weighted Model)
(Regression Coefficients, All Statistically Significant at the .001 level)

Variable	Cars		Trucks	
	Fuel Economy	Product Sales	Fuel Economy	Product Sales
2003	.0662	15456	.982	10120
2004	1.084	-148	.482	-5090
2005	1.758	16763	.869	-16488
2006	2.377	3936	.879	-24092
Fuel Economy	na	945	na	.823
R^2	.56	.32	.24	.12

Control variables: engine (horsepower, displacement, cylinders), body weight, wheel base, interior volume); transmission type, drive ratio, dynamometer setting;
all coefficients are significant at the .05 level or higher

Truck sales were down 24,092 in 2006, compared to 2002; controlling for all the other factors, car sales were up 3,936. For trucks, the effect was large in 2003, declined in 2004 and rebounded in 2005 and 2006. We also find that fuel economy was positively related to product sales. We find the negative effect on truck/SUV sales in 2004, 2005, and 2006, with the effect growing larger over time. This is consistent with the CBO findings. In addition to the shift from trucks to cars and after controlling for all the other factors, a one mile per gallon increase in fuel economy resulted in an additional sale of just under 1,000 more cars and trucks for each model.

CONCLUSION

Over the past three or four years there has been a dramatic shift in the auto market, a shift that is not, but should be, reflected in NHTSA's approach to setting fuel economy standards. The automakers and NHTSA are looking backward, but consumers are looking forward. If the desire and willingness of consumers to purchase more fuel efficient vehicles were fully recognized in NHTSA's analysis, it would have proposed a much higher standard because erroneous assumptions about consumer attitudes constrain the extent to which fuel savings technologies influence the standard. Correcting underlying economic assumptions of the proposed fleet wide fuel economy rules for 2011-2015 would result in a higher range of alternatives examined in the DEIS, and greater environmental benefits as a result.

In our comments in this proceeding, we concluded that NHTSA should raise the standard to its "optimized plus 50" alternative, which we call the "50-50 standard."[13] With the economic flaws corrected, we concluded that the benefits to the nation of higher standards required NHTSA to move to at least that level. It was a close call between that level and the even higher level of total benefit equals total cost (TB=TC). Although we argued that total benefit equals total cost standard is economically practicable by definition, there were two considerations that suggested the "50-50 standard" was preferable. First, for 2011, NHTSA's estimate of the level of fuel economy that would be achieved (as opposed to the level at which the standard would be set) under the "TB=TC" and the "50-50" approaches was not very different. Second, this was the case because there was a higher level of individual auto manufacturer failure to achieve the higher standard (70% v. 50%).

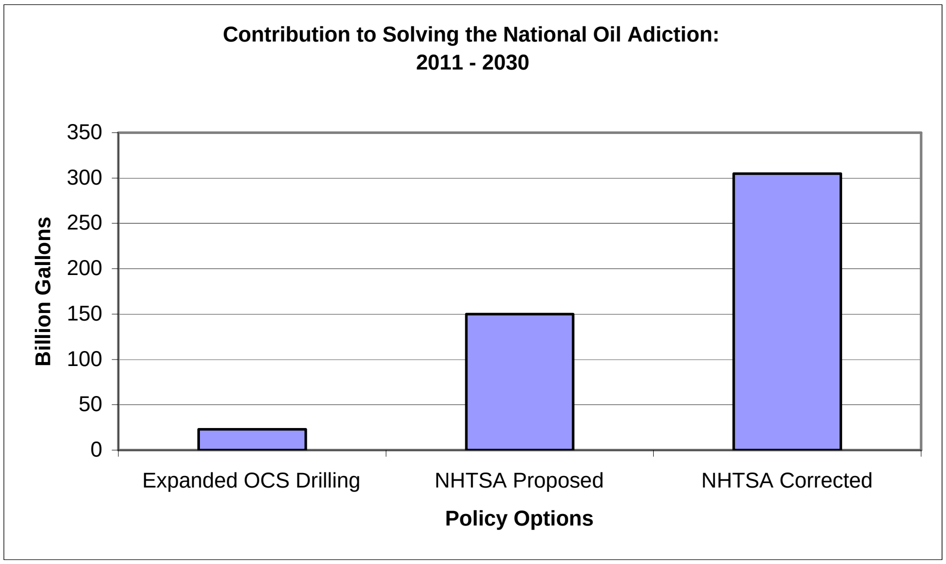
In light of the recent evidence on consumer and automaker behavior, we no longer believe that those two considerations are valid. Given the strong consumer interest in higher fuel economy and the dramatic changes in auto industry plans, if NHTSA sets a standard to lead the industry to higher level of fuel economy as it is required to do under the law, higher levels of fuel economy will be achieved and fewer auto makers will fail the "TB=TC" standard than previously anticipated by NHTSA. Indeed, when NHTSA revisits the fundamental assumptions in its model that slow the inclusion of fuel savings technology in the vehicle fleet, which have been called into question by developments in the market, it will arrive at a much higher level for standards across the board, but particularly for the "technology exhaust" and "TB=TC" scenarios. The old "TB=TC" level will become the new "50-50" standard.

There is no doubt that moving the standard to the higher level that we recommend is well worth the effort. To appreciate the importance of making such an improvement, we can put the impact of a higher fuel economy standard into context. The intense debate over expanded drilling on the Outer Continental Shelf (OCS) provides a useful context for understanding how important the setting of fuel economy standards is to the overall solution to the nation's oil addiction.

[13] Consumer Federation of America, "Comments and Technical Appendices," in National Highway Traffic Safety Administration, Notice of Proposed Rulemaking, Average Fuel Economy Standards, Passenger Cars and Light Trucks: Model Years 2011-2015, Docket No. HNTSA 2008-0089, RIN 2127-AK29, July 1, 2008.

Last year, the Energy Information Administration analyzed the increase in oil production that would result from allowing drilling in areas of the OCS that are currently unavailable for drilling.[14] EIA reckoned that production would not start until 2012 and would increase overall domestic production by 1.6 percent in the period between 2012-2030, which is .7 percent of the total consumed over the period. This is equal to approximately 23 billion gallons (see Exhibit 13).

Exhibit 13



Source: Calculated by author, based on Energy Information Administration, *Impacts of Increased Access to Oil and Natural Gas Resources in the Lower 48 Federal Outer Continental Shelf*, (available at http://www.eia.doe.gov/oiaf/aeo/otheranalysis/ongr.html); Office of Regulatory Analysis and Evaluation, *Corporate Average Fuel Economy for MY 2011-2015: Passenger Cars and Light Trucks* (National Highway Traffic Safety Administration, April 2008.

The level at which NHTSA should set the standard TB=TC would yield energy savings of over 300 billion gallons of gasoline between 2011 and 2030. NHTSA's proposed "optimized" standard would about half that.[15] Thus, a vigorous fuel economy standard would save 13 times as much oil as expanded drilling in the OCS. NHTSA's weak standard leaves a massive amount of oil savings on the table. Setting fuel economy standards to maximize fuel savings must be the cornerstone of ending our addiction to oil, but the Administration has failed in this vital part national energy policy.

Comment Docket No. NHTSA-2008-0060

Statement of Vice Admiral Dennis McGinn, USN, Retired
National Highway Traffic Safety Administration
Public Hearing on Proposed Fuel Economy Rulemaking
Washington, DC, August 4, 2008

Mr. Chairman, Ladies and Gentlemen, Thank you for the opportunity to share views which are based on over thirty-five years of service to the Nation in the United States Navy and as a senior executive presently involved on a daily ba with the science and technology of energy, transportation and the environme

I thank you for the opportunity to appear before you today to discuss the pro fuel economy rule, and the draft environmental impact statement aimed to pr a detailed analysis of potential impacts on energy resources, air quality and climate. As stated in your Federal Register announcement of this hearing the EPCA sets forth extensive requirements concerning the rulemaking to establis Model Year 2011–2015 CAFE standards. It requires the Secretary of Transportation to establish average fuel economy standards…. and, when setting ''maximum feasible'' fuel economy standards, the Secretary is require to ''consider technological feasibility, economic practicability, the effect of oth motor vehicle standards of the Government on fuel economy, and the need o United States to conserve energy.''

Today, I'd like to focus on that last requirement and, specifically, on the multi national security costs of our present level of oil dependency. In the interest time and in consideration of the many witnesses scheduled to appear before I want to give you my bottom line up front: Our continued dependence on oil constitutes a clear and present danger to our national security — economicall militarily and diplomatically.

These dangers involve real, quantifiable costs – and these costs do not appea be included in your assumptions for the proposed fuel economy rule. As a res your draft environmental impact statement is, at best, incomplete and, more importantly, fundamentally flawed by its reliance on outdated data and unsupported assumptions about the real costs of this nation's ever-growing consumption of oil.

Ignoring these costs is not just a mistake; it is a threat to our national securit because it precludes fuel savings our citizens and nation critically need at this moment in our history.

Our burgeoning demand for oil weakens U.S. diplomatic leverage around the globe, burdens our armed forces and leaves the U.S. economy vulnerable to unpredictable price spikes and an ever-growing trade imbalance. Taken toget these dynamics create a daunting national security challenge that must be m immediately.

• With oil at $130 a barrel, over a million dollars a minute is draining out of o country, increasing our trade deficit, creating huge opportunity costs and, mo significantly, putting money into the hands of regimes that are hostile to our interests.

• Terrorist networks have openly called for, planned and carried out attacks o global oil infrastructure because they know oil is the economic lifeblood of the U.S. and the world's economy. Former Republic National Committee Director Communications Clifford D. May wrote, "Every time we fill the tanks of our ca with gasoline we put money in the pockets of terrorists intent on killing Americans." (SHNS) Diversity can Pave 1/25/07

• OPEC recently warned that oil prices would experience an “unlimited” increa in the event of a military conflict involving Iran over its nuclear program.

• A very real consequence of such a confrontation is that Iran, in a bid to pre or respond to U.S. military action, would close the Strait of Hormuz, the Persi Gulf chokepoint through which 20 percent of the world's oil supply passes. Th impact would be swift and sure: unprecedented spikes in oil costs and a deep lasting effect on the US and world economy.

• Recently Venezuelan President Hugo Chávez and Russian President Dmitri A Medvedev declared that their countries would more closely coordinate their actions on global oil and gas markets and that they would work together on foreign policy, a sphere in which both countries have sought to counter Ameri influence. (NYT) EO Russia and Venezuela 7/23/08.

The economic impact of our oil dependency also threatens national security.

• We lose over $36 billion from our economy every month and oil imports nov account for over half of our Nation’s trade deficit. Our economy is exposed on daily basis to oil price shocks and supply disruptions. Regardless of how they caused, by global market dynamics, natural disasters, terrorist attacks, or politically motivated oil embargoes, the trends of our growing oil demand in a “business as usual” mode will make those price shocks much more frequent deeply felt and longer lasting.

Finally, there are national security costs involved in addressing global climate change.

• Top retired three and four star military leaders in a report from the Center f Naval Analysis, global warming poses a "serious threat to America's national security", acting as a "threat multiplier for instability" in some of the world's r volatile regions, adding tension to stable regions, worsening terrorism and lik dragging the U.S. into fights over water and other resource shortages.

Beyond these hard to quantify but clearly growing global environmental costs there is the military price tag – much easier to directly calculate – to protect s lanes, military bases of operations and maintaining continuous high level of forward presence simply to insure continued importation of oil.

• The US Military commits significant resources to protect energy supplies in some of the most volatile regions of the world. Our fine men and women in th Armed Forces serve our nation with honor, protecting American interests throughout the globe. The major focus of their activities for nearly thirty year centered in the Middle East, a region from which so much of the instability, st root causes of terrorism and Persian Gulf oil flow.

There have been multiple studies conducted that estimate the simple military externality costs for a gallon of gasoline, ranging from a low of .12 a gallon tc $8 a gallon. In my considered judgment and, based on a number of objective studies, the added cost is over $2.50 per gallon. I also believe that is very lik conservative number.

Vehicles directly account for more than 40 percent of our oil dependency, whi why Congress passed the Energy Independence and Security Act, and why increased higher fuel economy standards are at the heart of that act. It is the most effective, indeed, the only effective, regulation to curb oil consumption.

Congress set a floor, not a ceiling on CAFE standards. Your rulemaking is intended to take a host of factors into account into to set the right level.

Assuming there are no military costs to our dependence on oil is not only wro it is dangerous.

Throughout our history, Americans have successfully met critical challenges ir both war and peace. Building a new, clean energy economy has become one (the great challenges of our time.

The key questions for this hearing are: How will the actions on CAFE by this Agency and this Administration be viewed in ten or twenty years? Will we be a to look back and say that a bold, comprehensive and enlightened mandate produced substantial oil savings, increased our national security, helped our economy and significantly reduced carbon emissions?

We have less than ten years to change our oil dependency course in significar ways. Our Nation's security depends on the swift, serious and thoughtful response to these challenges and by the significant impact your deliberations rule making will have on carrying out the intent of our elected leaders in Cong

Thank you, Mr. Chairman, Ladies and Gentlemen.

Comment Docket No. NHTSA-2008-0060

Statement of Adam Lee, President, Lee Auto Malls
National Highway Traffic Safety Administration
Public Hearing on Proposed Fuel Economy Rulemaking
Washington, DC, August 4, 2008

Mr. Chairman, Members of the Committee, Ladies and Gentlemen, it is an hor to appear before you today.

My name is Adam Lee and I am president of Lee Automalls located throughou the state of Maine. I am a 3rd generation car dealer; I have been in this busir my whole life.

Our company was founded in 1936 by my grandfather, with a small Chrysler dealership. Today we have two Chrysler dealerships, a GM dealership and a Honda, Nissan and Toyota Dealership.

We are the number one seller of Hybrid cars in the state of Maine. We are als the largest Dodge and Jeep dealer in the state. Last year we sold approximate 7,000 new and used cars.

I am not an economist, nor am I a scientist. I don't know how to build a car o an automobile plant however for most of my life I have been selling new and cars and trucks. I still talk to customers every single day.

I came to Washington today because when I listen to the news, I sometimes like I must be the only person in the car industry actually talking to real customers.

Here is what I am hearing every single day:

How long a wait for a Prius?
Do you have any Honda Fit's in stock?
Do you have any Toyota Yaris' in stock?
Why doesn't Chrysler offer a car that gets 30 mpg?

Or the other type of calls I get.

What is my Tundra worth?
Can I get rid of my Suburban?

The answers to these questions are simple: The wait for a Prius is 6 months. have no Fits or Yaris' and your Suburban is not worth enough for you to be ab trade out of it.

Consumers want to buy vehicles that get more than 30 miles per gallon. I am just talking about hybrids. Car dealers have people waiting for good old-fashi small cars that get good fuel economy.

They have been demanding them for years with very few choices, and almost choices from Detroit. This is not a new situation; but with gas at $4.00 per ga the demand is overwhelming and the lack of choices dramatic.

When you talk to real customers, or stand in any of our showrooms it is hard to have a real sense of doom.

The average age of the new trucks and SUVs sitting on my lot is over 200 day old. Do you have any idea how expensive it is to have hundreds of trucks and

SUVs sitting around for 7 months?

Our big Chrysler dealership in Portland Maine has 1/2 as many sales people a we had around a year ago. We have fewer people working in our office and se department as well. They are no longer employed because we don't have the to sell that people want to buy. This means fewer salespeople frequenting the corner store, the dry cleaners, and the hardware store. It is bad for the econo

General Motors just announced a loss of $15.5 billion, and Ford just announce an 8.7 billion dollar loss. Standard and Poor's just lowered the Detroit threes credit rating to junk status and even Toyota who can do no wrong is shutting its' truck plant in Texas for three months. What they are doing is not working

So how did we get here?

In 1975 Congress mandated our first fuel economy standards. Unfortunately i the last 20 years these standards have not changed a bit. NHTSA could and should have done more.

So while the rest of the world increased the fuel economy of their fleets the U did nothing. Currently Japan and the European Union have fuel economy standards roughly double the U.S.'s. They must know something we don't.

I believe our lack of progress is largely a regulatory failure.

Anyone who watches the auto industry knows that the manufacturers have ne done anything in the name of safety or the environment unless they are force Whether it is seatbelts, airbags, or catalytic converters: Detroit has always insisted that they could not pay for them; until it becomes mandated: at whic point you would think they invented the word "unleaded gas."

NHTSA plays a real role in determining what our fuel economy will be. You analyze the impact of CAFE on Detroit. I think that your assumptions are base on incorrect data. Gas costs $4.00 a gallon, not two. The new technologies ar coming down in price. Clean diesels are now viable, plug in hybrids are on the horizon, and consumers have changed their habits and view of the future.

Now is the time for NHTSA to act. Don't drag your feet; don't look to Detroit f answers, look to the American consumers. They are demanding change.

They have cleaned our shelves of small cars. And they are desperate to trade their gas-guzzlers.

I have been selling Prius' since they came out 7 years ago. And since that tim every Toyota dealer has been selling them for list price and making a very nic profit on them. Demand is so strong that people stopped negotiating. This is a car dealers dream. A car people want so badly they don't negotiate.

It is frustrating to have a car sell this well and not have enough of them. I cu have a waiting list for a new Prius of 42 people that is a 6-month wait. I cann blame Toyota for having a hit. I can blame Detroit for not having one.

If you want to know how bad it really is, go read Automotive News. This is ou trade journal that is generally on the side of Detroit; I can assure you that th have few environmentalists on their staff.

"It is distressing the some automakers are back in Washington whining about meeting new fuel economy standards at a time when their customers are demanding vehicles that exceed the regulatory mandates," Automotives News editorial, July 14, 2008.

These cars, that Detroit bet their future on and my future, are not selling.

For over 70 years my family has been selling American made cars. I am the t generation running this family business. My 11 son thinks he will do what his father, grandfather and great grandfather did to earn a living: sell American c Will there be anyone left still making cars in Detroit?

WE NEED YOUR HELP.

Table of Contents

I. Introduction

On July 2, 2008 the National Highway Transportation Safety Administration (NHTSA) published a notice of availability for the draft environmental impact statement (DEIS) for the proposed Corporate Average Fuel Economy (CAFE) standards for model years 2011-2015. 73 Fed. Reg. 37922. According to the notice, comments are due by August 18, 2008. Id.

The DEIS purports to respond to the Ninth Circuit's ruling in *Center for Biological Diversity v. NHTSA*, 508 F.3d 508 (9th Cir. 2007), overturning the standards for model years 2008-2011 and accompanying Environmental Assessment, in part for failing to consider the rule's impact on climate change, especially with regard to tipping points. *Id.* at 554. The rule at issue set "unreformed" light truck standards of 22.5 mpg for MY 2008, 23.1 mpg for MY 2009, and 23.5 mgp for MY 2010. 71 Fed. Reg. 17566, 17587 (April 6, 2006). In 2011, the standards were to be "reformed" so that fuel economy standards were based on vehicle footprint, resulting in an average fuel economy of approximately 24 mpg for MY 2011. *Id.* at 17624.

After these standards were struck down in *Center for Biological Diversity*, the NHTSA issued the current proposed rule to establish fuel economy standards for cars and light trucks MY 2011-2015. The proposed rule would result in the average fuel economy standards, in mpg, shown below.

Table 1: Proposed Fuel Economy Standards for MY 2011-2015 (in mpg). From 73 Fed. Reg. 24352, 24355 (May 2, 2008).

	MY 2011	MY 2012	MY 2013	MY 2014	MY 2015
Passenger Cars	31.2	32.8	34.0	34.8	35.7
Light Trucks	25.0	26.4	27.8	28.2	28.6
Average	27.8	29.2	30.5	31.0	31.6

Two months later, the NHTSA issued the instant draft environmental impact statement for the proposed rule (DEIS). 73 Fed. Reg. 37922 (July 2, 2008). The DEIS considers seven alternatives, from keeping fuel economy standards fixed at 2010 levels to a level defined by NHTSA as "technology exhaustion" pursuant to the Volpe model. See DEIS at 2-6 to 2-10. The fuel economy standards for MY 2015 under each alternative are shown below.

Table 2: CAFE Standards for the seven alternatives analyzed in the DEIS, from CAFE MY 2011-2015 Passenger Car and Light Truck PRIA (April, 2008). Each value is the harmonic average of car/light truck standards.

	MY 2011	MY 2012	MY 2013	MY 2014	MY 2015
Alternative 1	25.3	25.3	25.3	25.3	25.3
Alternative 2	27.1	28.0	29.4	29.8	30.2
Alternative 3 (preferred)	27.8	29.3	30.6	31.0	31.6
Alternative 4	28.5	30.6	31.5	32.2	33.0
Alternative 5	29.2	31.7	32.6	33.4	34.5
Alternative 6	30.6	33.9	34.4	35.7	37.3
Alternative 7	31.1	35.1	38.7	39.6	41.4

These comments supplement and incorporate by reference our July 1, 2008 comments on the proposed rule. The DEIS is fatally flawed as an informational document. As set forth fully below, its principal defects include the following:

- The DEIS does not conform to the statutory requirements of the National Environmental Policy Act, 42 U.S.C. §§ 4321 *et seq.* (NEPA) and the Energy Policy and Conservation Act, 49 U.S.C. §§ 32902 *et seq.* (EPCA);
- The NEPA analysis fails to comply with recent caselaw regarding environmental review of climate change impacts;
- The NHTSA has failed to consider the full, reasonable range of alternatives that is mandated by NEPA;
- The direct/indirect impacts analysis is incomplete, factually and procedurally flawed, and presented in a manner that unlawfully minimizes the apparent importance of the alternatives;
- The cumulative impacts analysis does not properly account for cumulative actions and is presented out of context;
- The NHTSA failed comply with the consultation provision of section 7 of the ESA;
- The inadequate environmental analysis is another example of the current Administration's active opposition to GHG regulations.

II. The NEPA Analysis Must be Conducted Consistent with the Underlying Statutory Scheme

The NEPA analysis must be conducted in a way that is both meaningful and appropriate given the underlying statutory scheme. The EPCA requires that NHTSA set fuel economy standards for each model year at the "maximum feasible" level, taking into account four factors: technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy. 49 U.S.C. § 32902(f). The EPCA is a "technology-forcing" statute, whereby a challenging standard encourages technological innovation.[1] As part of the statutory balancing, NHTSA must necessarily determine what is "technologically feasible." The NHTSA has discretion to set standards somewhere below that level based on its consideration of the three other statutory factors, <u>if it is reasonable to do so.</u>

In December 2007, Congress passed the Energy Independence and Security Act of 2007 (Pub. L. 11-140, 121 Sat. 1492 (Dec. 18, 2007) (EISA)). The EISA eliminates the previous 27.5 mpg standard for passenger cars with a mandate that NHTSA set separate passenger car and light truck standards annually at the "maximum feasible level," with a <u>minimum</u> fleetwide fuel economy of 35 mpg by 2020.

The NHTSA has also violated NEPA because the NEPA analysis has not informed the EPCA balancing and the Volpe model – rather, the NHTSA has done a post-hoc EIS on the "black box" number from the Volpe model. The federal NEPA regulations are clear on the order in which decisionmaking must proceed:

[1] At the time of passage, the Senate Commerce Committee remarked that "[t]he establishment of fuel economy standards for the next 10 years creates the necessary climate for investment in automotive technology leading to substantial energy conservation." S.Rep. No. 179, 94th Cong., 1st Sess. 9 (1975).

> The statement shall be prepared early enough so that it can serve practically as an important contribution to the decisionmaking process and will not be used to rationalize or justify decisions already made (§§ 1500.2(c), 1501.2, and 1502.2). For instance: ... ((d) For informal rulemaking the draft environmental impact statement shall normally accompany the proposed rule.

40 C.F.R. § 1502.5. *See also, Pit River Tribe v. U.S. Forest Service*, 469 F.3d 768, 785 (9th Cir. 2006) (reviewing relevant statutes and holding that a post-hoc EIS does not cure failure to complete an EIS before lease extensions were granted; "The purpose of an EIS is to apprise decisionmakers of the disruptive environmental effects that may flow from their decisions at a time when they retain a maximum range of options.").

The structure, methodology, and contents of the DEIS are at odds with the both NEPA and the underlying EPCA and EISA statutory scheme. See 40 C.F.R. § 1500.2(a). The DEIS has failed to analyze a reasonable range of alternatives, failed to adequately disclose the direct, indirect, and cumulative impacts of NHTSA's action, has presented the information in an inaccurate and misleading fashion designed to minimize the impact of the rulemaking, and is inadequate in numerous other ways as described fully below.

III. The NEPA Analysis Must be Conducted in Accordance with Applicable Caselaw, including *Massachusetts v. EPA* and *Center for Biological Diversity v. NHTSA*

Recent court decisions have shaped the context in which the NEPA analysis must be conducted with regard to global warming. The United States Supreme Court held in *Massachusetts v. EPA* that carbon dioxide and other greenhouse gases are "unquestionably 'agents' of air pollution" and unambiguously fall within the Clean Air Act's definition of an air pollutant. 127. S.Ct. 1438, 1460 n. 26 (2007). Furthermore, the Court held that the EPA could not avoid its statutory obligation to regulate greenhouse gases merely due to "some residual uncertainty" about the "various features of climate change." *Id.* at 1463. This holding underscores that priority that must be given to addressing climate change despite the lack of some details. The excessive use of "uncertainty" in the DEIS violates this mandate to act on what is already known.

The Court dismissed concerns about applying the statute to climate change, a phenomenon little known at the time of enactment: "[T]he fact that a statute can be applied in situations not expressly anticipated by Congress does not demonstrate ambiguity. It demonstrates breadth." *Id.* at 1462 (quoting *Pennsylvania Dept. of Corrections v. Yeskey,* 524 U.S. 206, 212 (1998)). Likewise, in the present case, both NEPA and EPCA are broad statutes that are well-suited to address climate change. Thus, the DEIS must thoroughly analyze greenhouse emissions and global warming.

An agency must regulate even if the result of the regulation will be only an "incremental" step towards solving the climate crisis. The Supreme Court noted that "[a]gencies, like legislatures, do not generally resolve massive problems in one fell regulatory swoop... [t]hey instead whittle away at them over time." *Mass. v. EPA* at 1457. Nonetheless, the court notes that "[j]udged by any standard, U.S. motor-vehicle emissions make a meaningful contribution to greenhouse gas concentrations and hence, according to petitioners, to global warming. *Id.* at 1457-58.

Moreover, the NHTSA's duty to set fuel economy standards in no way conflicts with the EPA's duty to regulate emissions from automobiles. "The two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency. *Mass. v. EPA* at 1462.

The NHTSA must be further guided by the Ninth Circuit's opinion in *Center for Biological Diversity*, 508 F.3d 508. The court found a proper alternatives analysis is crucial to properly assess the impact of a project on global warming. The court reprimanded the NHTSA for failing to adequately consider a reasonable range of alternatives: the NHTSA had presented only alternatives that were derived from its cost-benefit analysis and that covered a limited range of fuel economy standards. 508 F.3d at 551. The court explained that "[s]ince EPCA's overarching goal is energy conservation, consideration of more stringent fuel economy standards that would *conserve more energy* is clearly reasonably related to the purpose of the CAFE standards. Energy conservation and environmental protection are not coextensive, but they often overlap." *Id.* at 552.

The court also found the cumulative impacts analysis is particularly important: "[t]he impact of greenhouse gas emissions on climate change is precisely the kind of cumulative impacts analysis that NEPA requires agencies to conduct." *Center for Biological Diversity,* 508 F.3d 508, 550. The Court faulted the cumulative impacts analysis for failing to "discuss the *actual* environmental effects resulting from those emissions or place those emissions in context of other CAFE rulemakings." *Id.* at 549 (emphasis in original). The court also noted that "the fact that climate changes is largely a global phenomenon that includes actions that are outside the agency's control... does not release the agency from assessing the effects of *its* actions." *Id.* at 550 (internal quotes removed).

An EIS was required because the effects of fuel economy standards "*may have* a significant impact on the environment." *Id.* at 553 (emphasis in original). The court expressed particular concern with regard to the non-linear aspect of "irreversible adverse climate change" or "tipping points" wherein a seemingly small change in emissions can evoke a dramatic climate response. *Id.* at 554. This indicates that seemingly small increments between alternatives can not be disregarded as insignificant.

While the court allowed the cost-benefit approach, it cautioned against reliance on earlier caselaw that supported use of the cost-benefit analysis: "[the cases] were decided two decades ago, when scientific knowledge of climate change and its causes were not as advanced as they are today. The need of the nation to conserve energy is even more pressing today than it was at the time of EPCA's enactment." *Id.* 530.

In addition, the Ninth Circuit warned against "undervaluing benefits and overvaluing costs of more stringent standards" in the cost-benefit analysis. *Id.* at 531. In particular, the court rejected the analysis because it failed to place a monetary value on the "most significant benefit" of reducing carbon dioxide. *Id.* The court denied uncertainty as a basis for failing to monetize carbon dioxide reductions: "while the record shows there are a range of values, the value of carbon emissions reduction is certainly not zero." *Id.* at 533.

IV. The DEIS Fails to Consider a Reasonable Range of Alternatives

The heart of an environmental impact statement (EIS) is the alternatives analysis. 40 C.F.R. § 1502.14. Yet, the NHTSA has unreasonably limited the considered alternatives so that the DEIS fails to capture the true range of possibilities. In particular, the DEIS fails because: (1) the range of NEPA alternatives is unreasonably constrained by the Volpe model; (2) the range of NEPA alternatives is unreasonably constrained by NHTSA's incorrect and unlawful assumptions regarding the model inputs, and (3) NHTSA has failed to consider one or more "technology forcing" alternatives.

A. The Volpe model unlawfully constrains the alternatives such that there is no true "technology exhaustion" alternative

The NEPA analysis must be conducted in a way that is both meaningful and appropriate given the underlying statutory scheme. The EPCA requires that NHTSA set fuel economy standards for each model year at the "maximum feasible" level, taking into account four factors: technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy. 49 U.S.C. § 32902(f).

As part of the statutory balancing, NHTSA must necessarily determine what is "technologically feasible." While NHTSA has discretion to set standards somewhere below that level based on its consideration of the three other statutory factors, if it is reasonable to do so, NHTSA violates both EPCA and NEPA by failing to even consider or disclose what is truly "technologically feasible." An essential component of the DEIS must be disclosure of the "technologically feasible" fuel economy level, along with the environmental impact of choosing this level of fuel economy as compared to the NHTSA's preferred alternative and a reasonable range of additional alternatives. The DEIS fails to provide both the basic starting point for this analysis and the proper analysis that must follow.

"Technologically" is defined by Merriam-Webster's Dictionary as "of or relating to a capability given by the practical application of knowledge." Merriam-Webster Online Dictionary (2008) (definition 1b for technology). "Feasible" is defined as capable of being done or carried out." *Id.* (definition 1). Therefore, NHTSA must disclose what practical application of the knowledge [in the area of engineering] is capable of being done or carried out. NHTSA has failed to do so.

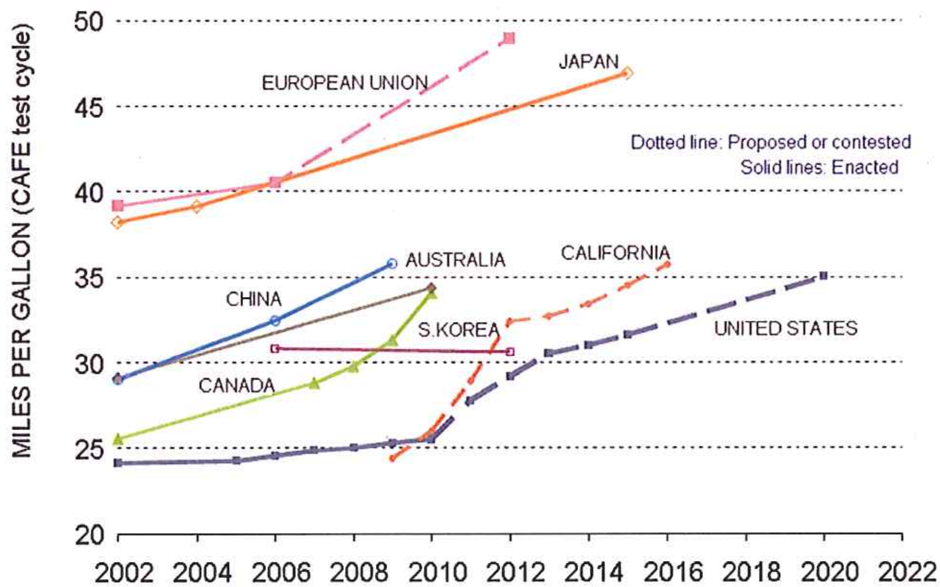
Table 3: Fuel economy standards for the "technology exhaustion" option, from CAFE MY 2011-2015 PRIA, Appendix A (April 2008).

Year	Car Standard	Light Truck Standard	Combined Standard
2010	27.5	23.5	25.3
2011	38.6	25.9	31.1
2012	45.4	28.6	35.1
2013	48.9	32.2	38.7
2014	50.1	33.1	39.6
2015	52.6	34.7	41.4

NHTSA's "technology exhaustion" would result in average fuel economy of 31.1 mpg in 2011 to 41.4 mpg in 2015. It is clear that this cannot, by any stretch of the imagination, be equated with what is "technologically feasible." First, cars on the road in the US today already achieve approximately the same or better gas mileage than what NHTSA has defined as the combined fleet "technology exhaustion" for model year 2015. These include the Toyota Prius (48/45; city/highway) and the Honda Civic Hybrid (40/45; city/highway).[2] Even more vehicles cars already achieve the "technology exhaustion" standard for the combined fleet in MY 2011: smartcar (33/41; city/highway); Mini Cooper (28/31); Toyota Yaris (29/36); Toyota Corolla (28/37); Nissan Altima Hybrid (35/33); Toyota Camry Hybrid (33/34); Hyundai Accent (27/32); Kia Rio (27/32); Mazda Tribute Hybrid 2WD (34/30); and Honda Fit (28/34).[3]

Second, NHTSA's "technology exhaustion" alternative results in fuel economy standards, even in 2015, which are below current standards in many other countries, and far below Japanese standards for 2015. In contrast, Europe and Japan had average fuel economy standards of approximately 40 mpg in 2006—over 15 mpg higher than U.S. standards. (ICCT 2007). Both Europe and Japan are predicted to continue increasing their fuel standards; even their high standards are not the technology maximum. That other countries have achieved higher fuel standards indicates that there are eminently feasible technology options available today that have not been included in the DEIS.[4]

Figure 1: Actual and Projected Fuel Economy for New Passenger Vehicles by Country/Region, 2002-2022. Source: *Passenger Vehicle Greenhouse Gas and Fuel Economy Standards: A Global Update*, ICCT (updated August 7, 2008).



By contrast, NHTSA's definition of "technology exhaustion" is the level that would "require every manufacturer to apply every feasible fuel saving technology to their MY 2011-2015 fleet." DEIS at 2-2. By what sleight of hand does NHTSA transform what is "technologically feasible" into

---

[2] Estimates from *Model Year 2008 Fuel Economy Guide*, DOE/EE-0321, *available at* http:www.fueleconomy.gov.

[3] Id.

[4] We note the substantial overlap in manufacturers of the European fleet and U.S. fleet (ICCT 2007:13), and that at least one manufacturer, Ford, has already declared its intention to "make big changes to the vehicles it sells domestically" and bring "six small cars made in Europe to the North American market (Smith 2008)".

something called "technology exhaustion" that is so much lower? The answer lies in the unlawful constraints of the Volpe model itself.

As discussed in our July 1, 2008 comments on the NPRM, the Volpe model makes a number of assumptions that are unreasonable and conflict with the EPCA statutory scheme. For example, the NHTSA assumes that the US fleet mix will not change in response to consumer demand for more fuel efficient vehicles or due to a change in regulatory requirements. 73 Fed. Reg. 24394. This assumption is particularly outrageous. First, auto manufacturers who have for decades deliberately manipulated the market with advertising, incentives, financing schemes, and other methods towards the least fuel efficient vehicles, continue to do so. (See, e.g. Chevrolet Tahoe Hybrid website; GreenCar.com 'Chevrolet Tahoe Hybrid Green Car of the Year;' Chrysler $3 gas banner; KCRA.com 'Chrysler $3 gas;' Ford Escape Hybrid website; Lyons 'Ford Guilt Free SUV'). Consumer preferences, nonetheless, are now shifting dramatically towards more fuel efficient vehicles in response to higher gas prices. (Cooper 2008). For a manufacturer to change its fleet mix in response to regulation is a method of compliance that must be considered in both the EPCA and NEPA analyses. Any precedent to the contrary is inapposite.

The NHTSA also assumes that manufacturers will not update their vehicle models more frequently than once every 5 years, and, "in most instances" has simply "accepted the projected redesign periods from the companies who provided them through MY 2013" 73 Fed. Reg. 24386. In other words, the underlying analysis for a fuel economy standard which is supposed to conserve energy by pushing manufacturers to develop new technology and innovate to meet challenging standards which may even "appear impossible" today, is constrained by the assumption that manufacturers will do nothing other than what they are already doing, at least for a period of five years. This clearly violates both EPCA and NEPA. On a related note, the the Volpe model generally does not apply a new technology until a given vehicle is due for a "redesign or refresh," and assumes that some technologies, such as hybrid vehicles, already in use today cannot yet be adopted. 73 Fed. Reg. 24386.

All of these unreasonable assumptions lead to NHTSA's exclusion of an essential piece of information from the DEIS: the technologically feasible fuel economy level. Thus, the NHTSA failed to consider a reasonable range of alternatives as required by law. *See, e.g., Friends of Southeast's Future v. Morrison*, 153 F.3d 1059, 1065 (9th Cir. 1998).

B. Even were the alternatives not unlawfully constrained by the Volpe model in the first instance, the NHTSA's use of unreasonable model assumptions prevented the consideration of a reasonable range of alternatives

Even were the Volpe model not fundamentally rigged to provide an unreasonably low result, the inputs used by NHTSA ensured that the fuel economy levels that resulted were artificially low, again resulting in NHTSA failing to analyze a reasonable range of alternatives.

The NHTSA also abuses its discretion to balance the four EPCA factors by using inaccurate and unreasonably constrained values in the Volpe model. As discussed below, in each and every instance when NHTSA faced a choice of inputs, it chose the level that would minimize the resulting fuel economy level. Even if one or more of the NHTSA's choices were otherwise lawful under EPCA and the Administrative Procedures Act (APA), which they are not, the NHTSA's failure to disclose in the DEIS the impact of these input choices, and to provide an alternative based on choosing higher input numbers, violates NEPA as well.

Moreover, even if NHTSA's choice of the "optimized" alternative were otherwise lawful, the use of incorrect inputs in the model results means that even by the NHTSA's own twisted definitions, this alternative does not actually represent the point at which marginal benefits equal marginal costs. The NHTSA's inaccurate claim that it does violates NEPA's requirement to provide accurate information to the public.

1. The Use of a 7% Discount Rate is Unreasonable

One of the primary flaws is the use of a 7% discount rate. The DEIS acknowledges that discount rate and gasoline price have a significant impact on the cost-benefit analysis. Yet the DEIS adopts a 7% discount rate and does not present even the results for a 3% or lower discount rate. The significant influence of discount rate alone is reflected in the fact that the "optimized" fuel economy standard with a 3% discount rate is more than 50% higher than the "optimized" alternative presented in the DEIS. PRIA Appx. A at A-2, Table A-1. This important information is only available in the Preliminary Regulatory Impact Assessment (PRIA), which is insufficient. *Grazing Fields Farm v. Goldschmidt*, 626 F.2d 1068, 1072 (1st Cir. 1980) ("no indication in the [NEPA] statute that Congress contemplated that studies or memoranda contained in the administrative record, but not incorporated in any way into an EIS, can bring into compliance with NEPA an EIS that by itself is inadequate.").

The choice of a 7% discount rate is not supported by the evidence. As the DEIS states, OMB suggests the use of both 3% and 7% discount rates, with the 3% discount rate appropriate where the costs of regulations are likely to be passed on to consumers. DEIS at 3-60. The Volpe model assumes that costs will be passed to consumers. For instance, the cost of new technology is limited by consumer pay-back periods and willingness to pay higher vehicle prices. See, e.g., DEIS 2-1 (discussing "retail price equivalent"); DEIS Appx. C at V11-41 (discussing impact of higher costs on sales).

Other agencies have assumed discount rates of 3% in similar analyses. The EPA in its recent advance notice of proposed rule making for regulating greenhouse gas emissions under the Clean Air Act noted that changes in GHG emissions are "essentially long-run investments" that "yield returns in terms of avoided impacts over a period of one hundred years and longer. Furthermore, there is a potential for significant impacts from climate change, where the exact timing and magnitude of these impacts are unknown. These factors imply a highly uncertain investment environment that spans multiple generations." 73 Fed. Reg. 44354, 44414 (July 30, 2008). When there are important benefits or costs that affect multiple generations of the population, EPA and OMB allow for low but positive discount rates (e.g., 0.5–3% noted by U.S. EPA, 1–3% by OMB)." *Id.*

In recent testimony before the House of Representatives Energy Committee, Sir Nicholas Stern notes the inappropriateness of pure-time discounting in which future generations are valued less than the current generation (Stern 2008). He goes on to distinguish between current market rates, which reflect only near-term benefits, versus the value of "young or unborn" generations. *Id.*

The DEIS thus makes several crippling errors in its choice of discount rate. First, the NHTSA assumes that a substantial portion of the costs of the regulation will come from foregone capital investments by the auto industry. This is simply incorrect. All capital costs will be passed onto consumers in short order. Furthermore, the largest costs from the regulation come in the form of impacts from catastrophic climate change. This will most certainly be felt by consumers, both in this generation and the next. The choice of a 7% discount rate is based in part on assumptions regarding loan rates. DEIS Appx. C at VIII-2. Yet, this short-sighted context is entirely inappropriate. Given that the impacts of the alternatives are analyzed out to year 2100, the discount rate must also reflect this long time horizon for impacts.

2. The Cost of Fuel is Unrealistic

Another major determinant of the output from the Volpe model is the cost of fuel. DEIS at 2-2. The NHTSA used the EIA's Annual Energy Outlook Early Release Forecast to select fuel prices, and assumes future fuel prices ranging from $2.26 per gallon in 2016 to $2.51 per gallon in 2030. Considering that national average gasoline prices are currently $3.81 per gallon [5] and over a dollar higher than one year ago, there is every indication that the price of oil will continue to increase over the short term, and there is every indication that the price of oil will continue to remain in the short term higher than projected by the administration, this estimate is impossible to justify. It is important to note that these price projections are based in 2006 dollars, and include Federal, State, and local taxes. However, the estimated 2008 fuel price of $2.69 per gallon of gasoline in 2006 dollars, adjusted by a 3% estimated annual inflation rate, is approximately $2.85 per gallon of gasoline, far below the current prices and projections. The use of an inappropriate gasoline price projection greatly skews the results, since the savings in fuel expenditures are by far the largest components of the cost-benefit analysis, accounting for $2.27 of the $2.51 in net benefits from each gallon of gasoline reduced, overwhelmingly drives the conclusions of the cost-benefit analysis as constructed by NHTSA.

3. The Cost of Carbon has No Basis in the Facts

The NHTSA's methodology for the selection of an estimate of the value of reducing greenhouse gas emissions is arbitrary and designed to minimize the estimate. The Volpe model assumes that the value of CO_2 reductions is the midpoint between a so-called "high" of $14/ton CO_2 and a "low" of $0/ton CO_2. DEIS Appx. C at VIII-30. This valuation is flawed because: (1) it is based on an out-dated and otherwise flawed analysis; (2) the use of a $0 low value is unjustified; and (3) simply splitting the difference between two values does not take into account the distribution of economic projections for the cost of carbon.

The NHTSA relies entirely on the 2005 *Energy Policy* article, Tol (2005), as the source for the estimate of $14 per ton of CO_2, but fails to address the much higher estimates also reported by Tol. Tol (2005) states that "The marginal damages caused by a metric ton of carbon dioxide emissions in the near future were estimated in the [IPCC] Second Assessment Report at US$5-125 per tC." In addition, the NHTSA overlooks the fact that the studies cited in the Tol (2005) survey dated back as much as 18 years, to 1991, and 25 of the 28 studies cited were published more than five years ago. Considering that

[5] EIA current prices, *available at* http://www.eia.doe.gov/oil_gas/petroleum/data_publications/wrgp/mogas_home_page.html (value for August 11, 2008).

the understanding of climate change has expanded dramatically in the past five years, and that impacts of climate change are progressing much more rapidly than were previously projected, this represents a fatal flaw in the analysis. Of the 28 papers cited by Tol (2005), only three were published since 2003, only one of which was peer reviewed. That paper estimated the social cost of carbon as high as $14 per ton of CO_2. (Pearce 2003).

The Fourth Assessment Report of the Intergovernmental Panel on Climate Change also refers to the Tol (2005) survey, but is careful to point out, on page 813 of Yohe (2007), that "[it] is likely that the globally-aggregated figures from integrated assessment models underestimate climate costs because they do not include significant impacts that have not yet been monetized...," and, on page 17 of Adger (2007), that "taken as a whole, the range of published evidence indicates that the net damage costs of climate change are likely to be significant and to increase over time." The NHTSA concedes this point: "[taken] as a whole, recent estimates of the SCC may underestimate the true damage costs of carbon emissions because they often exclude damages caused by extreme weather events or climate response scenarios with low probabilities but potentially extreme impacts, and may underestimate the climate impacts and damages that could result from multiple stresses on the global climatic system." DEIS Appx. C at VIII-28.

In fact, the IPCC, on page 813 of Yohe (2007), estimates the cost of carbon as high as $350 per ton of carbon ($97.67/ton CO_2), and states that "It is virtually certain that the real social cost of carbon and other greenhouse gases will increase over time; it is very likely that the rate of increase will be 2% to 4% per year."

The DEIS places great weight on the fact that the IPCC Fourth Assessment report cites to Tol (2005). Yet, the DEIS does not acknowledge the many other studies that the IPCC refers to. For example, the IPCC contrasted the Tol estimate of carbon costs with that of Downing (2005), which indicated that the lower benchmark of $50/tC ($13.95/t CO_2) was reasonable. Most importantly, the IPCC gives great weight to the estimates in the Stern Review 2007. As the most recent and most comprehensive analysis of the costs of climate change, the Stern Review is the best available information. As the IPCC notes, the Stern Review 2007 estimates the cost of carbon at $85/t CO_2. The NHTSA must re-calibrate the Volpe model results to reflect the actual range of values in the current literature.

The NHTSA also uses an impermissible value for the lower bound on the cost of carbon dioxide reductions. The DEIS acknowledges that the IPCC indicates that the costs of global climate change will be non-zero. DEIS Appx. C at VIII-30. But then it jumps to the amazing and illogical conclusion that "it does not necessarily rule out low or zero values for the benefit to the U.S. itself from reducing emissions." *Id.* This statement is completely erroneous. The evidence is clear that the U.S. will be severely adversely affected by climate change. Just a few examples: some of the most expensive real estate and most densely populated regions are along our expansive coastlines; the desert Southwest is gripped by drought and projected to continue to be; much of our fresh water is supplied by annual snowpack, which is already declining; forest fires are raging through most of the forested regions of the country; and human health, especially in the Southwest where there are large retired populations, will be affected by extreme heat events and in many other ways. Furthermore, our economy depends heavily on imports and exports from other countries. If the rest of the world is economically harmed by climate change, the U.S. will undoubtedly pay. There is no doubt that the U.S. will suffer severe impacts along with the rest of the world: the cost of carbon is most certainly non-zero.

Finally, the DEIS uses an impermissible method for reducing the range of potential carbon costs to a single value. The DEIS takes the midpoint between its chosen "upper" and "lower" bound. But as emphasized by the IPCC there are numerous estimates of carbon cost. This constellation of carbon costs will have some distribution. It is very likely that the estimated values do not fall along a normal "bell" curve. Consequently, taking the midpoint between the extreme values does not reflect the true "consensus" value for the cost of carbon.

The NHTSA must first re-analyze the available and current estimates of the cost of carbon, with particular attention to the leading analyses in the Stern Review 2007. Next, the NHTSA must ascertain a proper non-zero lower bound for its estimates. Finally, the distribution of estimated values should be taken into account when a single value is selected for use in the Volpe model.

4. The Volpe Model Fails to Account for Changes in Fleet Mix and Market preference

The low CAFE standards have allowed United States automakers to pursue the profits associated with large, expensive trucks and SUVs, at the expense of the consumer and the environment. This market plan has proven untenable even to the automakers and their workers, with Ford posting an $8.7 billion loss in the second quarter of 2008, and GM closing four truck and SUV plants (NPR Big Three, Dwyer (NPR) Ford Shifts). Now the United States automakers are forced to attempt to catch up to consumer demand for higher fuel efficiency vehicles. One domestic automaker has attempted to obscure its paucity of fuel-efficient vehicles by offering consumers a special credit card that caps the cost of gasoline at $2.99 per gallon for three years (KCRA Chrysler $3 gas). Other domestic automakers have launched disingenuous advertising campaigns promoting trucks and SUVs with marginally higher fuel efficiencies, even though those higher-efficiency vehicles are being produced only in extremely small quantities and are not actually available in many markets (NPR Hybrid SUV, Ford Escape, Chevy Tahoe). That is, the U.S. automakers are currently responding to the changing market demand not by producing higher efficiency vehicles, but by offering advertising and gimmicks. This problem has been greatly facilitated by decades of stagnant CAFE standards, and can hardly be expected to be resolved by the Volpe model that relies so heavily on the marketing plans and short-sightedness of the automakers.

Fleet mix is a central component of average fuel economy and yet is absent from the Volpe model cost-benefit analysis. For instance, the Volpe model "does not attempt to account for…intentional over-compliance…Another possibility NHTSA and Volpe staff have considered but do not yet know how to analyze, is the potential that manufacturers might "pull ahead" the implementation of some technologies in response to CAFE standards that they know will be steadily increasing over time." Proposed CAFE Standards MY 2011-2015 at 73 Fed. Reg. 24352, 24393 (May 2, 2008).

This failure is particularly glaring in today's auto market. The media is full of stories of automakers that are facing poor economic returns on low-mileage vehicles and as a result shifting to smaller, more fuel-efficient models. Ford motor company, for instance, has plans to reduce SUV production and begin offering some of its European fuel-efficient vehicles for sale in the U.S. (Smith

2008). A recent report by the Consumer Federation of America indicates that the NHTSA's assumed fleet mix does not represent what consumers are actually buying (Cooper 2008). Furthermore, the average consumer desires a car that gets at least 32.7 mpg today (Cooper 2008), yet even the "technology exhaustion" alternative would only require an average fuel economy of 31.1 mpg in 2011. Including this shift in consumer demand in the Volpe model is essential to properly assess the potential for increased fuel economy in the U.S.

The NHTSA does not address the potential implications of a changing automobile market and to embrace its technology forcing mandate. The possibility that increasing consumer demand for more fuel efficient vehicles may affect the calculation of an individual automaker's CAFE under Reformed CAFE, and the opportunities available for individual automakers to take advantage of those changing demands through CAFE credits. 73 Fed. Reg. at 24393 & 24443. However, the proposed CAFE standards completely fail to consider the significant market advantage experienced by automakers that "pull ahead" to offer higher-efficiency vehicles.

In such a market, "overcompliance" can result in significant gains in market share and economic returns for innovative automakers. By failing to consider shifting consumer demand, NHTSA and the Volpe model significantly underestimate the economic benefits of increased efficiency vehicles, and artificially and inappropriately skew the cost-benefit analysis of developing and implementing efficiency technologies. Stated another way, NHTSA has illegally constrained its analysis by locking itself into the assumption that a manufacturer's fleet mix need not, and will not, change in response to the nation's need to conserve energy.

5. The Cost-Benefit Analysis Does Not Include All Available Technologies

The potential technologies for improving fuel economy are unreasonably limited. The extent to which the technology is unreasonably limited is amply illustrated by the fact that the "technology exhaustion" alternative barely reaches the <u>current</u> fuel economy standards in Japan and Europe, much less the projected fuel economy standards in Europe and Japan for 2015. *Supra* Table 3, Figure 1. A model that predicts maximal technology implementation to be unable to reach even current market standards in other countries is clearly not considering all available technologies.

Concrete examples of technologies that are unreasonably excluded are: electric vehicles, plug-in hybrids, and power-split hybrids. Electric vehicles are entirely excluded from the Volpe model. 73 Fed. Reg. at 24381, Table III-3. This is absurd considering that a major U.S. auto manufacturer produced and placed such vehicles on the road in the year 1996.[6] These vehicles were pulled from the market for commercial reasons over loud protests of drivers in 1999, and destroyed in 2003. (Biederman 2005). An auto manufacturer's commercial decision does not render a technology unsuitable for implementation—the only concern should be physical capability, which has been clearly demonstrated. Plug-in hybrids are also categorically excluded on the basis that they are not "market-ready" (73 Fed. Reg. at 24381), despite the fact that Toyota is planning to introduce plug-in hybrids by MY 2010. (Maynard 2008). The major U.S. auto manufacturers are also planning to offer similar vehicles around the same time. *Id.* Powersplit hybrids, like the Toyota Prius, are considered advanced technology that will not be available

[6] See http://www.sonyclassics.com/whokilledtheelectriccar.

under 2014. 73 Fed. Red. At 24381, Table III-3. This assumption is ludicrous given that the Toyota Prius has been sold in the U.S. since MY 2001 and is a top-selling vehicle.

Other technologies that are not yet commercially available, but could be if economy standards were sufficiently high, include replacement of spark-plugs with laser-pulse injection systems and engines that can switch between two-stroke and four-stroke modes. (Graham-Rowe 2008). Furthermore, the DEIS makes no mention of alternatives such as compressed-air vehicles. (Green Car Congress 2008).

There are abundant potential technologies for improving fuel economy that have not been included in the Volpe model. This leads to misleading and factually incorrect outputs from the model, and a failure to disclose basic relevant information under NEPA.

6. The Volpe Model Impermissibly Constrains Implementation Based on Manufacturer Development Cycles

The NHTSA has ignored the EPCA technology-forcing mandate by limiting technology implementation to manufacturer development cycles. As discussed in greater detail below in section IV(C), the EPCA is a technology-forcing statute. The principle of technology-forcing is that the market must be pushed to do more than it currently plans. Yet, the NTHSA disregards this principle when it limits technology implementation to manufacturer "redesign" and "refresh" cycles. 73 Fed. Reg. at 24385.

Manufacturers not only manipulate market demand as discussed above, but also respond to it. When economics demand, a manufacturer would certainly implement a change outside a normal development cycle. Similarly, if regulations required, automakers could make changes outside a normal development cycle. Development cycles are a product of commercial convenience, not practicability. As a result, they have no bearing on the considerations of technology implementation within the cost-benefit analysis.

In summary, in each and every instance discussed above, NHTSA unreasonably chose an input level that would depress the fuel economy level that resulted from the modeling. Then, NHTSA disclosed in the DEIS only the results of the modeling runs using these unreasonable input figures. NHTSA's modeling is arbitrary and capricious and violates NEPA (as well as the EPCA, as described throughout and in our July 1, 2008 comments on the proposed rule). Even if NHTSA's use of the Volpe model were otherwise valid (which it is not, as described above), at a minimum, NHTSA was required to consider alternatives based on modeling with reasonable inputs. In other words, NHTSA should also have disclosed the level of its so called "optimization" and "technology exhaustion" alternatives had the model been run with inputs that would have led to higher fuel economy outputs. NHTSA failed to do so.

Furthermore, the NHTSA makes the mistake of elevating the decisional process over the substantive character of the alternatives. As the court in *California v. Block* noted with regard to an EIS prepared under NFMA, "[a]lthough it is worthwhile to consider a broad range of variables in constructing policy alternatives, the procedure becomes meaningless if the variables are assigned numerical values such that only a limited range of outcomes result." 690 F.2d 753, 769 (9^{th} Cir. 1982). Here, NHTSA has limited its consideration, and range of alternatives, to the results of the model, yet those results are meaningless for a number of reasons, including the fact that the input values were simply incorrect. Thus, the range of values used as inputs to the Volpe model has unreasonably constrained the universe of alternatives under NEPA.

Moreover, as discussed above, the Volpe model arbitrarily constrains the universe of NEPA alternatives. The purpose of NEPA is to inform decision making, but application of a specialized tool designed for cost-benefit analysis indicates that a decision has already been made by the agency. If the cost-benefit analysis is applied to select alternatives, there is no potential for considering alternatives that may carry less environmental impact. Yet, the Volpe cost-benefit analysis was employed to define all alternatives, including the maximal technology alternative. This alternative was based on what the NHTSA "considered to be available" and based on market penetration rates defined in the Volpe model. DEIS at 2-10.

C. The NHTSA failed to include a "technology forcing" alternative

The EPCA is a "technology-forcing" statute, whereby a challenging standard encourages technological innovation. The EIS must consider alternatives in light of EPCA's technology-forcing character. As the court in *Center for Auto Safety v. Thomas* noted, "[t]he experience of a decade leaves little doubt that the congressional scheme in fact induced manufacturers to achieve major technological breakthroughs as they advanced towards the mandated goal." 847 F.2d 843, 870 (D.C. Cir. 1988) (overruled on other grounds); *see also Green Mt. Chrysler Plymouth Dodge Jeep v. Crombie*, 508 F. Supp. 2d 295, 358-359 (D. Vt. 2007) (discussing technology-forcing character of EPCA and the use of increased fuel efficiency to augment performance rather than mileage). As explained by the court in *Kennecott Greens Creek Min. Co. v. Mine Safety and Health Admin.*, "when a statute is technology-forcing, the agency can impose a standard which only the most technologically advanced plants in an industry have been able to achieve-even if only in some of their operations some of the time." 476 F.3d 946, 957 (D.C. Cir. 2007) (quoting *United Steel Workers of America, AFL-CIO-CLC v. Marshall*, 647 F.2d 1189, 1246 (D.C. Cir. 1980). With regard to a similarly technology-forcing statute, the Clean Air Act, legislative history indicates that the primary purpose of the Act was not "to be limited by what is or appears to be technologically or economically feasible," which may mean that "industries will be asked to do what seems impossible at the present time." 116 Cong. Rec. 32901-32902 (1970), 1 Legislative History of the Clean Air Amendments of 1970 (Committee Print compiled for the Senate Committee on Public Works by the Library of Congress), Ser. No. 93-18, p. 227 (1974); *see also Whitman v. American Trucking Associations*, 531 U.S. 457, 491 (2001).

Due to the technology-forcing nature of the statutory scheme, the NHTSA was required to include one or more technology-forcing alternatives in the DEIS. Such an alternative would include standards that may appear impossible today, but that would force innovation as industry strives to meet a challenging standard. NHTSA's "technology exhaustion" alternative, defined by the criteria "whether a particular method of improving fuel economy can be available for commercial application in the MY for which the standard is being established" (DEIS at 1-2) clearly cannot substitute for consideration of a technology-forcing alternative.

While NHTSA will likely argue that it was not required to consider a technology-forcing alternative because it has pre-determined that it would not select such an alternative, it is clear that all reasonable alternatives, even those falling outside the lead agency's jurisdiction, must be considered. *Natural Resources Defense Council. v. Morton*, 458 F.2d 827, 834 (D.C. Cir. 1972). Because EPCA is a technology-forcing statute, the failure to include a technology-forcing alternative was unreasonable and unlawful.

Having failed to include such an alternative, the NHTSA then failed to analyze the environmental impacts of a technology-forcing standard. This omission is particularly significant because such a technology forcing standard would have environmental benefits that not only amplify the ability of automakers to meet higher standards in later years, but that also ripple through the economy. NHTSA's failure to consider this important aspect of the analysis renders the DEIS inadequate.

V. The DEIS's Analysis of Direct and Indirect Impacts is Fatally Flawed and Designed to Minimize the Effect of NHTSA's Action

The failure to evaluate a reasonable range of alternatives is compounded by the DEIS's inadequate analysis of direct and indirect impacts. Fundamental purposes of the EIS include providing a meaningful discussion of the environmental problem, the agency's contribution to that problem, available solutions, and the agency's contribution to those solutions. The DEIS is lacking any such meaningful analysis. Instead, with regard to global warming, the analysis is systematically skewed in a way that minimizes both the severity of the problem and the NHTSA's contribution to it. The DEIS is lacking any discussion at all of solutions, and how the NHTSA's actions either contribute to, or detract from, the implementation of such solutions. These flaws render the DEIS worse than useless as an informational document, because it is affirmatively misleading to the reader.

A. The DEIS Systematically Understates the Severity of the Climate Crisis and Overstates Scientific Uncertainty

The NHTSA has failed to present, as it must, information and analysis in a way that provides meaningful insight into the relevant environmental problems and available solutions. The information in the DEIS on climate impacts is presented in a misleading manner and without appropriate context. Under NEPA an EIS must be written in "plain language" so that decisionmakers and the public can readily understand [it]." 40 C.F.R. § 1502.8. The ultimate purpose of an EIS is to inform decisions. To do so, the information must not only be comprehensible to non-experts, but also present the context for the information in a manner that elucidates and explains the importance of each aspect of the decision.

The DEIS fails in this regard because it presents the information on the impacts of climate change in a way that minimizes the apparent potential for substantial harm. Even more problematic is the minimization of the apparent influence of each alternative on climate change. Throughout the DEIS the impact of each alternative as well as the difference between alternatives is presented as insignificant and meaningless. Although the DEIS mentions many of the potential consequences of increased atmospheric CO_2, the data is presented in a disjointed manner and qualified as "uncertain." Yet it has been decades since there has been any real scientific uncertainty regarding whether climate change is occurring as a result of increasing concentrations of anthropogenic (Oreskes 2004).

The reality is that, as discussed in previous sections, there is a substantial risk of climate disaster if U.S. greenhouse gas emissions continue unchecked. This collision course towards climate disaster can be avoided through efforts to reduce quickly reduce emissions. The transportation sector is one of the largest sources of emissions, and therefore also an essential part of the solution. Stringent CAFE standards can be part of one of the most significant components of a national greenhouse gas emissions reduction program. This substantial opportunity, however, is never explained to the reader, but rather, the reader is left with the impression that NHTSA's actions will make very little difference one way or another. This is profoundly misleading and violates NEPA's disclosure requirements.

The statement of "uncertainty" is overused and abused throughout the DEIS. To avoid further analysis and consideration of environmental impact, the DEIS frequently presents background on climate change, but qualifies the information as "uncertain." In most instances this is uncalled for. The argument could be made that every piece of information in any EIS is uncertain, yet an agency is expected to make a good faith effort to consider impacts that are reasonably certain. While the IPCC may label the intensity of some effects as "likely" as opposed to "very likely," the effects are still just as certain as effects such as smog due to criteria pollutant emissions. For instance, the IPCC states that "Warming of the climate system is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice, and rising global average sea level." (Alley et al. 2007). By overusing the uncertainty qualification, the DEIS fails to consider important impacts of climate change and obfuscates the issue so that the decisionmakers and public will not be able to adequately evaluate the balance of harms that may occur as a result of different alternatives.

One prime example of inadequate context and information is the analysis of abrupt climate change, or tipping points. The CEQ regulations require that an agency "describe the consequences of a remote, but potentially severe impact" based on credible scientific information. 50 Fed. Reg. 32234, 32237 (August 9, 1985). The DEIS acknowledges that the possibility of abrupt climate change exists, yet by asserting uncertainty downplays the significance of tipping points. This approach is untenable. While no one may be able to predict with certainty on exactly which date a threshold for abrupt climate change may be reached, there is ample evidence that unchecked greenhouse emissions will result in abrupt climate change. In fact, various studies have attempted to quantify when such a threshold may be reached. The most recent estimate by Hansen and colleagues is that prolonged time spent over 350 ppm CO_2 will result in catastrophic[7] impacts. Previous estimates considered 450 ppm the threshold for catastrophic climate change.

Given the certainty that abrupt climate change will occur above some level of atmospheric concentration, the alternatives must be analyzed in the context of avoiding catastrophic climate change.

B. The DEIS does not adequately address climate tipping points

[7] Although the climate literature often refers to "dangerous" levels of climate change to denote CO_2 concentrations above which climate impacts will be severe and irreversible, we use the term "catastrophic" here because current CO_2 levels have already surpassed the "dangerous" level of 350 ppm.

Among the many consequences of climate change, "tipping points" carry the greatest threat to wildlife, human welfare, and economic security. As such, it is of paramount importance that any federal action be executed in a manner that reduces the possibility of abrupt climate change.

The Volpe model is the sole decision-making tool used to balance the factors set out in the EPCA. It does not capture the costs of abrupt climate change or tipping points. One of the factors that NHTSA considers under EPCA when setting the fuel standards is "the need of the United States to conserve energy." Environmental implications of the need for large quantities of petroleum are included in this factor. One of the environmental effects of continued heavy petroleum consumption is the possibility of passing over "tipping point" thresholds, or catastrophic climate change.

Because this is an acknowledged possibility, it must be included in the NEPA analysis and the balancing of the EPCA factors. The DEIS concludes that the science surrounding tipping points is too uncertain to be included in the analysis. This is simply not true. It is well-accepted that there will be tipping points. (Meehl et al. at 775, 2007). A recent analysis of "tipping elements" indicates that contrary to the IPCC's conservative projections, there is a strong chance that tipping points will be crossed within this century. (Lenton et al. 2008). This study also indicates that it may be possible to identify thresholds for tipping points for the purposes of policy making. *Id.*

Furthermore, a recent study by Weitzman, an economics professor at Harvard, indicates that while traditional cost-benefit analysis can not properly capture the costs of climate change, including tipping points, a different analysis is more likely to capture the costs. (Weitzman 2007).

The economic impacts of climate change are astounding. The much-respected Stern Review, published in 2007, estimates that the costs of climate change will range from 5% to 20% of GDP. (Stern 2007). In contrast, the Stern Review estimated that rapid action to address climate change would only cost approximately 1% of GDP.[8] *Id.* In 2007, this would have corresponded to approximately $138 billion.[9] In contrast, the cost of inaction—abrupt climate change—has been estimated at over $400 billion.[10] (Bindschadler 2008). The message is clear: the U.S. can not afford to gamble with abrupt climate change.

Under all scenarios considered in the DEIS the atmospheric CO_2 concentrations would reach 550 ppm or greater—the "optimized" alternative would reach over 700 ppm. This is well above the threshold for abrupt and catastrophic climate change. As a result, no alternatives adequately address the need for deep reductions in CO_2 emissions.

The DEIS erroneously dismisses the potential for tipping points as an impact that will not occur this century and thus does not require consideration. The basis for this conclusory statement that abrupt climate change will not occur this century is a statement in the IPCC Fourth Assessment Report that

---

[8] As Sir Nicholas Stern explained in testimony before the House of Representatives Energy Committee, other major bodies such as the IPCC, McKinsey & Co., and the International Energy Agency have produced similar estimates. N. Stern, *Climate Change: Costs of inaction, Targets for Action* (June 26, 2008).
[9] National GDP obtained from file "gdplev.xls" downloaded from http://www.bea.gov/national/index.htm#gdp (last visited August 12, 2008).
[10] Cost for 1 m rise in sea level this century.

"[a]brupt climate changes … are not considered likely to occur in the 21st century, based on currently available model results." *See* DEIS at 3-53 (emphasis added; citing Meehl et al. 2007). Yet, it is well-accepted that climate models can not capture the dynamical processes that lead to climate instabilities and rapid shifts such as occur during abrupt climate change. See, e.g., DEIS at 3-52.

Model predictions consistently underestimate observed climate change, and thus very likely also underestimate when tipping points will occur. For a discussion and examples, see Hansen et al., *Target CO_2* at page 10 (2008). There are numerous examples of accelerated changes occurring well in advance of model predictions. One is the rapid rate of sea ice loss in the Arctic. The summer sea ice extent in 2007 shattered all records, dropping below the level that most models predicted would not occur until 2050.

Figure 2: Sea Ice Concentration for September 2007, along with Arctic Ocean median extent from 1953 to 2000 (red curve), from 1979 to 2000 (orange curve), and for September 2005 (green curve). September ice extent time series from 1953 to 2007 is shown at the bottom. Source: Stroeve et al. (2008: 13, Figure 1).

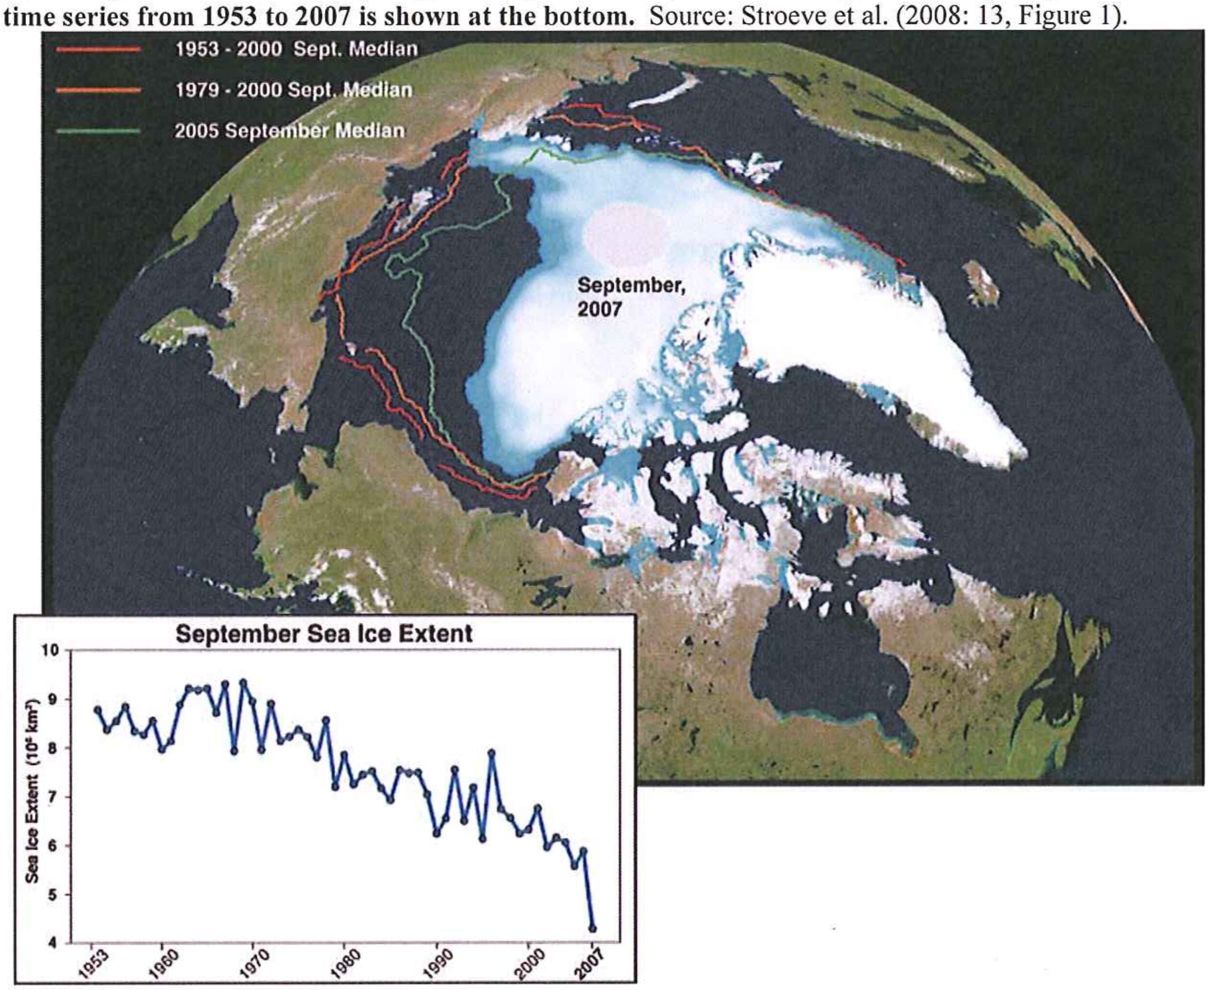


Figure 3: Arctic Summer Sea Ice Extent: Observations Compared to Model Runs. Source: After DeWeaver (2007); Stroeve (2007).

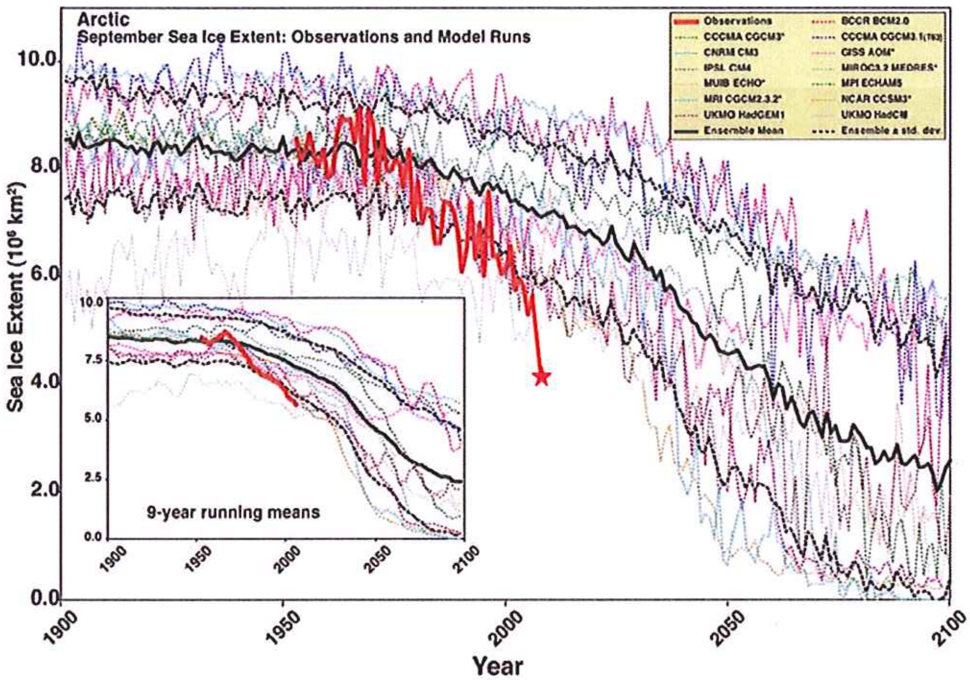


More recent models of Arctic sea ice predict that the Arctic could be sea-ice free by the summer of 2013. In a recent conference presentation, Professor Maslowski from the Naval Postgraduate School showed if current trends continue, the Arctic will be sea-ice free by 2013. (Maslowski et al. 2008). The summer sea ice predictions for 2008 suggest that the same precipitous decline may occur again,[11] with some scientists suggesting a 50:50 chance that the North Pole will be ice-free this summer.[12] Arctic sea ice is important both because of the albedo feedback effect and because sea ice melt leads to a warmer Arctic Ocean, which in turn accelerates the melt rate of the Greenland ice sheets.

The best basis for determining tipping points may be the use of paleoclimate data. Based on such data, Hansen and colleagues have estimated that remaining at CO_2 concentrations above 350 for a prolonged period of time is likely to invoke tipping points (Hansen et al. 2008). Paleoclimate data also indicate that in the past, at temperatures expected to be reached by 2100, Greenland and Antarctica contributed several meters to sea level. (Overpeck et al. 2006). The rate of rise at this temperature was approximately 1.6 m/century. (Rohling et al. 2008). Thus, the current CO_2 level of 385 ppm is not only "dangerous," but catastrophic and could lead to tipping points this century. No models, including those used by the IPCC, can capture the dynamic response of ice sheets or adequately predict current observations of sea level rise. (DEIS at 3-75; Rignot 2008).

---

[11] For up-to-date information on sea-ice extent, see the National Sea Ice Data Center (NISDC) Arctic Sea Ice News and Analysis, *available at* http://nsidc.org/arcticseaicenews/ (last visited August 12, 2008). The May 5, 2008 report explains why there is a greater than 50% chance that the sea ice extent for the summer of 2008 will actually be smaller than that in 2007. The August 11, 2008 report documents extensive, recent sea ice loss. The annual minimum will not occur until September.
[12] Alan Duke, *North Pole Could be Sea-ice Free this Summer, Scientists Say*, reported at CNN.com, *available at* http://www.cnn.com/2008/WORLD/weather/06/27/north.pole.melting/ (last visited August 12, 2008).

This is not an excuse, however, for the DEIS to dismiss this critically important issue. The DEIS cannot rely solely on model results to predict sea level rise. Instead, the prediction should be based on the sea level measurements from paleoclimate data, which indicate that in the past sea level was approximately 25 meters higher at temperatures only 2-3° C of warmer and atmospheric CO2 concentrations of 350 – 450 ppm. (Hansen 2007). For comparison, the DEIS predicts that temperature in 2100 under the A1B "business as usual" scenario will be approximately 2.7° C warmer. DEIS at 3-63, Table 3.4-5. Although the DEIS acknowledges that Rahmstorf (2007) has predicted a sea level rise of over 1 m by 2100, even his prediction does not capture the non-linearity of ice-sheet loss (Hansen 2007). If this non-linearity is taken into account, "business as usual" sea level rise this century is more likely to be on other order of 5 m (*Id.*; Overpeck et al. 2006).

Given the strong scientific evidence that sea level will rise by substantially more than predicted in the IPCC Fourth Assessment report, the EIS's analysis, both qualitative and quantitative, must be adjusted to account for the economic impacts of severe and abrupt climate change. It is certain that sea level will rise significantly this century, and assuredly at a rate much greater than that reported in the DEIS. Regardless of the actual numerical value, the amount of increase will be enough to constitute a major environmental and economic impact. Economic analyses exist to estimate the economic impact of such an event. (Stern 2007).[13] As a result, the DEIS must include the substantial economic cost in the cost-benefit analysis.

Reaching any single tipping point can bring severe economic and ecologic consequences. But perhaps more worrisome is the linkage between tipping points such that reaching one tipping point may in turn trigger a second. An example is the connection between Arctic sea ice and permafrost melt rates. Permafrost refers permanently frozen land; this surface stores large amounts of carbon. As permafrost thaws due to global warming, it releases carbon, often as methane. (Christensen et al. 2004). Methane has a global warming potential that is approximately 25 times greater than that of carbon dioxide over 100 years. The release of methane as permafrost thaws creates a positive feedback loop that may result in a climate tipping point. *Id.* Recent evidence indicates that the loss of Arctic sea ice, one tipping point, accelerates permafrost thaw, a second tipping point. (Lawrence et al. 2008). The multiplicative effect of reaching several tipping points on a similar time scale would drastically increase the costs associated with climate change.

C. The DEIS lacks any discussion of solutions

After summarizing an environmental problem, the next required task of an EIS is to discuss ways to reduce the project's impact and solve the problem. This rulemaking is particularly well suited for such an analysis since EPCA requires the fuel economy standard to be set at the "maximum feasible" level and higher fuel economy standards result in lower greenhouse gas emissions. Yet the failure to discuss solutions is one of the DEIS's most glaring failures.

In the bizarre and constrained world presented in the DEIS, there is no solution to global warming. The full range of alternatives considered by NHTSA, combined with NHTSA's assumptions, discussed below, result in atmospheric CO_2 concentrations of between 705.4 and 708.6 ppm. DEIS at 2-

[13] *Available at* http://www.hm-treasury.gov.uk/independent_reviews/stern_review_economics_climate_change/stern_review_Report.cfm.

16. While global warming is indeed a daunting problem, presenting the analysis in this truncated form leaves the false impression that nothing can be done about it, violating both the letter and the spirit of NEPA. Leading scientists are able to tell us with a high degree of certainty that allowing CO_2 concentrations to rise to more than 700 ppm by the end of this century will result in catastrophic climate impacts. NHTSA has a mandatory duty to disclose in the DEIS what NHTSA can do to contribute to the solution.

NHTSA's failure to do so flows in many ways from its failure to discuss a reasonable range of alternatives and conduct an adequate impacts analysis, as discussed above. NHTSA's failure to discuss more stringent alternatives precluded it from discussing how much smaller the environmental costs of those more stringent alternatives would be. But NHTSA also continued to improperly skew the analysis in additional ways as discussed below.

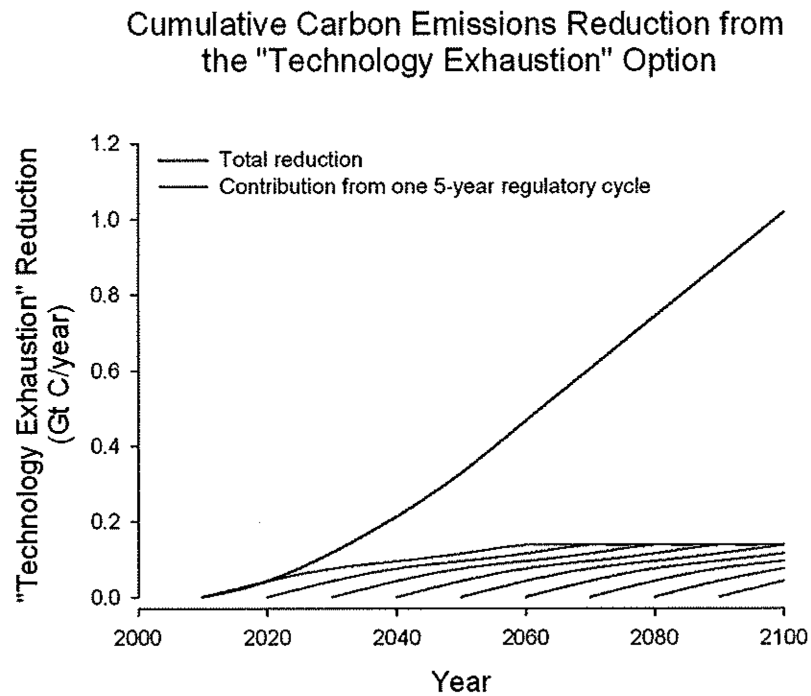
D. The DEIS impermissibly limits the analysis to assuming that future fuel standards will remain fixed at 2015 levels

One of the ways NHTSA minimizes the apparent impact of its rulemaking is to limit its analysis to a world in which fuel economy levels become fixed beyond the last year of the current rulemaking. To limit the analysis to this assumption is inconsistent with the statutory scheme, which of course requires that (1) fuel standards for the combined fleet reach a minimum of 35 mpg by 2020 and (2) the NHTSA set fuel standards must be set at the "maximum feasible level" each year. 49 U.S.C. § 32902(a); (b)(2)(C). This regulatory regime requires NHTSA to continue to raise standards each and every year through 2100. While the NHTSA may have been free to calculate and discuss the resulting environmental impact that would result from fixing the standard beyond the current rulemaking, disclosing only this piece of information was clearly not sufficient, especially given the statutory scheme that requires the NHTSA to continue increasing fuel economy to the maximum feasible level each year.

While the DEIS that the standards for 2011-2015 will impact the 2016-2020 standards, the DEIS improperly limits its analysis to the environmental impacts from the emissions of just those vehicles in the MY 2011-2015. Limiting the analysis in this manner allowed NHTSA to minimize the apparent impact of its action, because despite the fact that the lifetime emissions of these five model years of US vehicles will be massive, even this large chunk of emissions can be made to incorrectly appear insignificant if it is compared to a large enough number. In order to give a complete picture of this aspect of the problem, NHTSA should have compared its alternatives for model years 2011-2015 not just to the emissions that would result if fuel economy standards thereafter remained fixed, but also to the emissions that would result if fuel economy standards continued to improve along the trajectories established by each of a reasonable range of alternatives. Had NHTSA done so, the impact of its action would have appeared in a very different light. This is particularly true since technology innovation today will both amplify the gains that can be made in the auto industry in the future, and will also have spillover effects into other sectors of the economy. The NHTSA was required to address these issues in the DEIS, but failed utterly to do so.

Because of the application of technologies developed in response to a valid, technology-forcing CAFE standards to other sectors of the economy and in other countries, there should be a non-linear increase in projected reductions with increased stringency of fuel standards. The DEIS should have included an analysis of continual increases in fuel economy through year 2100. EPCA requires that *each year* the maximal fuel economy standard be established. It is certain that technology will continue to improve and thus that the maximum feasible fuel standards will continue to increase through 2100. As shown in the figure below, one way to estimate the emissions savings due to a continual increase in fuel economy would be to iteratively sum the projected reduction in CO_2 from the MY 2011-2015 standards (obtained from the difference between the "no action" and "technology exhaustion" alternative emissions in Table 3.4-2 of the DEIS) out to year 2100.

Figure 4: One potential mechanism for accounting for cumulative emissions reductions from continual compliance with the "maximum feasible" fuel standards requirement of EPCA. Each black line represents the reductions expected from a 5-year regulatory cycle. For illustrative purposes, the "technology exhaustion" reductions from DEIS Table 3.4-2 were used. The red line is the sum of reductions at each year. Year is shown on the abscissa, carbon emissions reduction per year is shown on the ordinate.



Employing this strategy results in a substantially greater effect than the artificial assumption in the DEIS that fuel economy will not improve after MY 2015. The cumulative carbon savings would be 39 Gigatons of carbon by year 2100, and a 15 ppm difference between "no action" and "technology exhaustion" in CO2 concentration in 2100. This value would be higher if the "technology exhaustion" option was not unreasonably constrained by the Volpe model. The DEIS doesn't include any information on this important issue.

The NHTSA then compounds the other errors in its analysis by presenting the effect of its action only as an improvement over the "no action" alternative, which NHTSA defines as leaving fuel economy standards unchanged. The true "no action" alternative is the technologically achievable fuel economy level. NHTSA's "action" is to reduce this level, based on its consideration of the other statutory factors. Therefore, NHTSA was required to disclose in the DEIS the additional greenhouse gas emissions that will result from its decision to set fuel economy standards far lower than the technologically feasible level. The NHTSA failed to do so, instead continuing to portray its rulemaking merely as an improvement over the status quo, when in fact the opposite is true: it has proposed standards that are far lower than what is achievable with today's and future technology, and far lower than current levels in other countries. The true effects of this decision must be disclosed.

Again, while NHTSA may have been free to quantify the environmental impacts that would result from fixing fuel economy standards at 2011 levels, including only this information and then analyzing only the difference between doing nothing and NHTSA's proposal, rather than the difference between NHTSA's proposal and the technologically feasible fuel economy level, violated NEPA.

E. The analysis of climate change resulting from each alternative is flawed

In addition to the structural flaws discussed above, the numerical results from the climate impacts analysis are invalid. Two methods are used to model the impact of each alternative: MAGICC 4.1 and a "scaling approach." DEIS at 3-50 & 3-51. The results from MAGICC are flawed because an old version of the software was used; the scaling approach is misleading and mischaracterizes climate impacts. Furthermore, the inputs to the MAGICC model were incorrectly constrained, as discussed above, by the Volpe model and thus the results do not represent the true climate impact of each alternative.

1. The presentation of MAGICC results creates the misleading impression that there is no difference between the alternatives.

MAGICC is used to estimate the increase in CO_2 concentration, global mean temperature, and sea level rise. The DEIS uses the SRES A1B-AIM scenario as a "baseline." The only comparisons in the DEIS are among the three SRES "business as usual" scenarios: B1, A1B, and B2. This analysis, however, is incomplete because it ignores the fact that in order to avoid catastrophic climate impacts greenhouse gas concentrations must be quickly reduced back to below 350 ppm. SRES A1B-AIM results in CO2 concentrations of 715 ppm in year 2100—far above dangerous CO_2 levels. A more appropriate comparison would be one of the "WRE" stabilization scenarios that are included in the MAGICC software. These stabilization scenarios are provided for 350 to 750 ppm stabilization.

Regardless of the baseline that is selected, the numerical results do not accurately reflect the state of the science. The DEIS relies heavily on the IPCC's Fourth Assessment Report, published in 2007. The model version used for numerical analysis, however, is calibrated to the Third Assessment Report, which was published in 2001. The MAGICC software has been updated to reflect the values reported in the Fourth Assessment report; the newest version is MAGICC 5.3. This update has important changes from version 4.1. These changes include:

- Values for climate forcings were updated and two new forcings for nitrates and land use were included
- The stabilization scenarios now include stabilization strategies for non-CO_2 gases as well as CO_2

- The method of sea level rise was improved to be more consistent with the IPCC Fourth Assessment Report
- Default climate sensitivity was changed from 2.6° C to 3.0° C, in conformance with the Fourth Assessment Report

Most importantly, the modeling results should be presented with the disclaimer that non-linear responses are not included in the predictions. Emphasis should be placed on the fact that (1) the model does not capture actual sea level rise predictions because it does not include ice sheet dynamics and (2) the model does not include the impact of rapid increases in methane from widespread loss of permafrost.

2. *The "scaling approach" is misleading and does not add any helpful information to the DEIS*

The "scaling approach" used in the DEIS is intended to test the effect of intermediate emissions scenarios. This is accomplished through linear interpolation between the relative outputs of three SRES scenarios: B1, A1B, and A2. This same estimate can be obtained by designating a "GAS" file in MAGICC that has intermediate CO_2 emissions.

From the skeletal description in the DEIS, it appears that (in a nutshell) the process involves taking the difference between the annual emissions (inputs) and the outputs (temperature, sea level, CO_2 concentration) associated with each of the SRES scenarios. The percentage change from "baseline" emissions for each alternative is then used to scale the outputs from the baseline scenario. See DEIS at 3-50. At a minimum, the calculation explanation must be improved, preferably with step-by-step examples to make the calculation accessible to the general public, as required by NEPA.

The underlying assumption to this process is that a linear transform will adequately describe the response to a change in emissions levels. Yet, as acknowledged in the DEIS at 3-52, climate interactions are non-linear. To test the linearity of the change between SRES scenarios, we ran an intermediate scenario in which the input annual carbon emissions were set at the midpoint between B1 and A1B. We then plotted the output variables. Examples are shown below. The numerical differences between each of the SRES scenarios and the intermediate scenario were not symmetrical. This indicates that climate outputs are not linearly related to emissions levels, violating the assumption of linearity upon which the scaling approach is based.

As acknowledged in the DEIS, the climate system is non-linear. DEIS at 3-52. Thus, it is not surprising that a linear transform between SRES scenarios is an inaccurate approximation of climate response.

Of course, comparing the scaling approach to MAGICC outputs assumes that MAGICC has accurately approximated the dynamics of the climate system. It seems likely, however, that MAGICC is the superior approximation. The MAGICC simulation routine has been extensively used by the IPCC and subjected to peer review. In contrast, no citations are provided in the DEIS that indicate the "scaling approach" has been subjected to similar scrutiny. Thus, the NHTSA should consider the MAGICC outputs more reliable. Furthermore, the DEIS provides no explanation why the "scaling approach" was deemed necessary.

In the following two figures, outputs from MAGICC are plotted as a function of year. In each plot, the values on the y-axes represent the difference between an SRES scenario (either B1 or A1B) and an "intermediate" scenario. The intermediate scenario was generated by creating a MAGICC "GAS" file that has emissions for each year that are the average of the emissions for B1 and A1B. One would expect that if there was a linear relationship between the change in outputs due to a change in inputs (emissions/year), these lines would overlap.

Figure 5: Difference in CO_2 Concentration between SRES Scenarios B1 and A1B and the "Intermediate" Scenario.

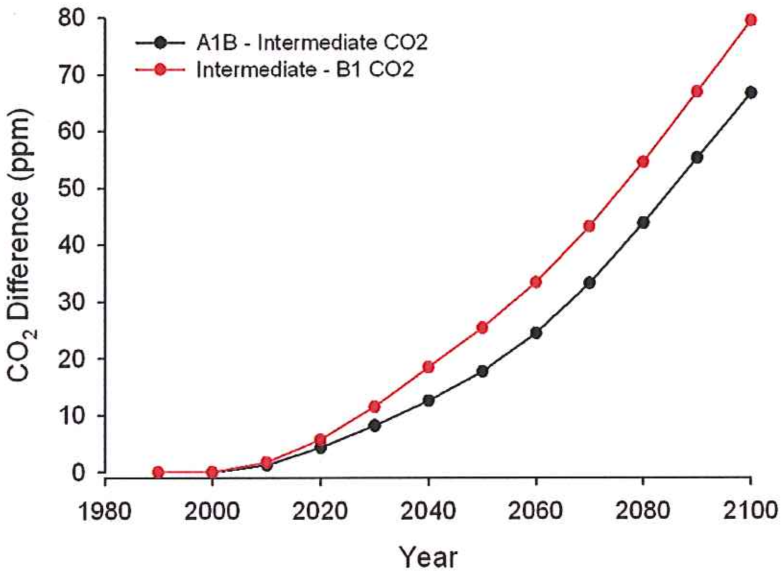


Figure 6: Difference in Temperature and Mean Sea Level between SRES Scenarios B1 and A1B and the "Intermediate" Scenario.

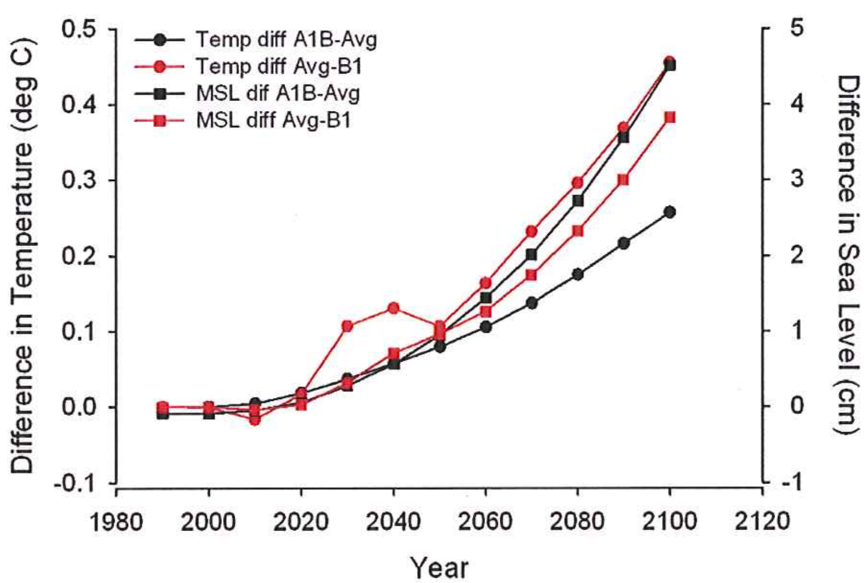

With regard to the scaling approach for temperature change, the results from the scaling approach indicate a smaller change in temperature at equilibrium than the MAGICC results [version 5.3]. Furthermore, if a comparison of temperature sensitivity is desired, this is easily accomplished by changing this one parameter in MAGICC. The "bounding analysis" for temperature change in 2100 is also unnecessary as one of the outputs of MAGICC is the temperature in year 2100. The temperature change for year 2100 as predicted by MAGICC is much larger than suggested by the "bounding analysis."

The "scaling approach" as applied to sea level is also misleading. First, MAGICC 5.3 reports increments of sea level rise of 0.1 mm – not 1 mm as reported in the DEIS. Thus, the MAGICC results can resolve sea level rise to the same precision as the "scaling approach."

The example of the scaling approach as applied to sea level and as illustrated in Table 3.4-14 is obscure and impossible to follow. Data appears to be missing from Table 3.4-14 (column 1) and the values do not appear to correspond to the steps outlined on page 3-77. This needs to be clarified so that readers can assess the validity of the numerical results. The value for sea level rise for "no action" corresponds to the midpoint for the B1 scenario (28.0 cm), not the A1B scenario (34.5 cm) that is purportedly represented in Table 3.4-14. If the steps provided on page 3-77 are carried out, it appears that the difference between alternatives for sea level rise is approximately double the range of values reported in Table 3.4-14.

Regardless, the approach itself is deeply flawed. First, using the IPCC estimates of potential sea level rise does not correct the shortcomings in MAGICC. The IPCC did not account for ice sheet dynamics in any of their estimates. As a result, any modeling or scaling attempt will not capture the most important components of sea level rise, as acknowledged in the DEIS at 3-76. As a result any attempt to estimate sea level rise from IPCC data will be deeply flawed. If a scaling approach is to be used, it should be based on paleoclimate data predicting the sea level rise associated with various temperature and CO_2 concentrations.

Second, the scaling approach purports to correct for "overstatements" due to inertia in the climate system. Yet any apparent "bias" is *created* by applying the "scaling approach" from the DEIS. If an accepted model such as MAGICC is employed, the effects of climate inertia will be properly accounted for without being overly represented in the results. Thus, the solution to "overstatements" of climate inertia is to avoid using the scaling approach.

Third, the scaling approach as applied to sea level change uses inaccurate values from Table 3.4-7, the temperature "scaling approach" results. When compared to the results from MAGICC at differing climate sensitivities, the scaling approach results in smaller differences in temperatures between alternatives. This in turn pollutes the results from the sea level scaling approach, making the sea level differences seem smaller.

F. The DEIS Fails to Adequately Address Ocean Acidification

The DEIS ignores one of the major, direct impacts of increased atmospheric CO_2: ocean acidification. Carbon dioxide is readily exchanged between the atmosphere and the sea surface. The increase in CO_2 is a direct result of human activity—fossil fuel burning. Due to the fact that the ocean has a carbonate buffer system, an increase in aqueous CO_2 reduces the concentration of carbonate while increasing the concentration of bicarbonate. The direct result is a decrease in ocean pH.

The reduction in free carbonate ions harms organisms that form calcium carbonate shells. There is a profound impact on the entire marine ecosystem due to the fact that many calcifying plankton, the basis of the food web, are severely affected by ocean acidification. Furthermore, organisms such as fish also experience direct effects from increased ocean CO_2, which include metabolic, immune, and reproductive dysfunction.

There is an extremely high level of scientific consensus regarding the destructive effects of ocean acidification. A recent comment letter signed by the top 25 marine scientists who study ocean acidification emphasized that the decrease in pH due to un-checked CO_2 emissions will be devastating and irreversible on human time scales (Caldiera and 25 others, 2007).

Ocean acidification has also been recognized by advisory bodies. For instance, the USCOP characterizes climate change as "among the most pressing scientific questions facing our nation and the planet." (USCOP Ocean Blueprint 2004). Furthermore, the USCOP report states that ocean acidification is impairing some organisms and has "potentially profound impacts on marine production and biodiversity." *Id.* The resulting recommendation is that scientific information be used to modify management strategies. Likewise, the Pew Commission discussed the myriad effects of climate change on marine life, including changes in ocean chemistry. The report stated that the Commission "feels strongly" that the U.S. must reduce its emission of greenhouse gases to limit injury to the marine environment. (Pew Oceans Commission Living Oceans, 2003).

The oceans have already taken up about 40% of the CO_2 that humans have produced since the industrial revolution, and this has lowered the average ocean pH by 0.11 units (Sabine et al. 2004). Although this number may sound small, it represents a significant change in acidity. The ocean takes up about 30 million metric tons of CO_2 each day (Feely et al., 2008). While preindustrial levels of atmospheric CO_2 hovered around 280 ppm (Orr et al. 2005)), they have now increased to 380 ppm; if current trends continue they will increase another 50% by 2030 (Turley et al., 2006). Over time, the ocean will absorb up to 90% of anthropogenic CO_2 released into the atmosphere (Kleypas et al. 2006).

Unlike future climate change, the pH change in response increased atmospheric CO_2 is relatively easy to predict because it involves basic chemical reactions and is unlikely to be affected by global temperature change (McNeil & Matear 2006). Thus, there is a strong consensus in the field that the oceans will undergo extensive acidification as the atmospheric CO_2 concentration rises.

Studies have established that anthropogenic CO_2 is the direct cause of the decrease in ocean pH. For instance, a tracer technique can be used to separate naturally occurring and dissolved carbon from that due to human activity (Gruber et al. 1996). Oceans absorb CO_2 more slowly than humans are currently releasing it. Current levels of anthropogenic CO_2 have virtually guaranteed that ocean pH will continue to decrease in the foreseeable future. Anthropogenic CO_2 emissions will result in a decrease in oceanic pH of 0.4 units by 2100 according to a model based on "business as usual" IPCC scenarios (Caldeira & Wickett 2003). This would constitute a catastrophic pH level (Zeebe et al. 2008). Disastrous impacts to marine ecosystems can only be avoided with rapid reductions in CO_2 emissions. *Id.*

Despite the strong scientific consensus and direct connection between CO_2 emissions and oceanic pH, the DEIS treats ocean acidification as an indirect, cumulative impact. This is unacceptable. The ecological impacts of the proposed CAFE standards on ocean acidification must be fully analyzed. Ocean acidification is even more predictable than changes in temperature or sea level rise, for instance. Yet, the DEIS makes no effort to quantify the influence of the alternatives on ocean pH. Furthermore, the DEIS fails to consider the economic costs of the collapse of the ocean food web. This cost must be included in any cost-benefit assessment conducted by NHTSA to accurately reflect the proper balance between the costs and benefits of reducing CO_2 emissions.

G. The DEIS Fails to Analyze the Impact of Black Carbon

Although the DEIS quantifies CO_2 emissions, it utterly fails to address black carbon, an important short-lived pollutant that contributes to global and regional warming. Black carbon is produced by incomplete combustion and is the black component of soot. Although combustion produces a mixture of black carbon and organic carbon, the proportion of black carbon produced by burning fossil fuels, such as diesel, is much greater than that produced by burning biomass. The CAFE standards will affect both gas and diesel engines, and may result in a higher percentage of diesel-fueled vehicles. Thus, it is essential to consider the impact of the new standards on black carbon emissions.

Black carbon heats the atmosphere through a variety of mechanisms. First, it is highly efficient at absorbing solar radiation and in turn heating the surrounding atmosphere. Second, atmospheric black carbon absorbs reflected radiation from the surface. Third, when black carbon lands on snow and ice, it reduces the reflectivity of the white surface which causes increased atmospheric warming as well as accelerates the rate of snow and ice melt. Fourth, it evaporates low clouds. Notably, black carbon is often complexed with other aerosols such as sulfates, which greatly increases its heating potential. (Ramanathan & Carmichael 2008; Jacobson 2001).

Due to black carbon's short atmospheric life span and high global warming potential, decreasing black carbon emissions offers an opportunity to mitigate the effects of global warming trends in the short term (Ramanathan & Carmichael 2008). Black carbon is considered a 'short-lived pollutant' (SLP) because it remains in the atmosphere for only about a week in contrast to carbon dioxide, which remains in the atmosphere for over 100 years. Furthermore, the global warming potential of black carbon is approximately 760 times greater than that of carbon dioxide over 100 years (Reddy & Boucher 2007) and approximately 2200 times greater over 20 years (Bond & Sun 2005). It is estimated that black carbon is the second greatest contributor to global warming behind carbon dioxide (Ramanathan & Carmichael 2008).

Unlike traditional greenhouse gases, which become relatively uniformly distributed and mixed throughout the Earth's atmosphere, black carbon exerts a regional influence. The impacts of black carbon on a regional level include both atmospheric heating, as discussed above, and hydrological changes. Hydrological changes occur due to alterations in cloud formation and heat gradients. *Id.* For instance, aerosol pollution has been linked to decreases in the summer monsoon season in tropical areas as well as the drought in the Sahel region of Africa. *Id.* Black carbon also impacts the drought-fire cycle. The more drought conditions prevail, the more forest fires burn, and the forest fires in turn emit massive quantities of black and organic carbon. The release of these aerosols intensifies the drought effect.

Another impact of black carbon is accelerated snowmelt; for instance, black carbon is likely contributing to the retreat of Himalayan glaciers and the resulting water shortage in areas of Asia. *Id.* When black carbon settles on snow, it makes the snow darker so that it absorbs more solar radiation. This directly leads to snow melt. In addition, local atmospheric heating due to black carbon increases the melting rate. These same effects may well be operating on mountain ranges in the U.S. such as the Sierra Nevada, which would reduce water availability throughout California, a highly populated region, at crucial times of the year.

Black carbon is also detrimental to human health. It has been linked to a variety of circulatory diseases. One study found an increased mortality rate was correlated with exposure to black carbon (Maynard 2007). The same is true for heart attacks (Tonne 2007). Another study found that residential black carbon exposure was associated with increased rates of infant mortality due to pneumonia, increased chronic bronchitis, and increased blood pressure (Schwartz 2007).

In developed countries, diesel burning is the main source of black carbon. Diesel emissions include a number of compounds such as sulfur oxides, nitrogen oxides, hydrocarbons, carbon monoxide, and particulate matter. Diesel particulate matter is approximately 75% elemental carbon. (EPA Diesel Health Assessment 2002). Furthermore, global inventories of emissions rates from a variety of sources exist to facilitate quantitative estimates. (See, e.g., Bond et al. 2004). Thus, it is crucial that black carbon be addressed in the DEIS.

1. Analyzing Particulate Matter is Insufficient to Address Black Carbon

Particulate matter (PM) refers to the particles that make up atmospheric aerosols. The primary constituents of PM are sulfates, nitrates, and carbon compounds. Sulfates and nitrates form in the atmosphere from the chemical reaction of sulfur and nitrogen dioxides. These may often be present as ammonium sulfate or nitrate salts. Carbon compounds may be directly emitted, e.g. black carbon emitted from combustion, or may form in the atmosphere from other organic vapors, e.g. oxidation of volatile organic compounds.

Because PM can be reduced through mitigation of other constituents of PM than black carbon, it is essential that black carbon emission reduction strategies be considered independently from PM reductions. The proportions of the constituents of PM vary over time and by location (see EPA Particle Pollution Report 2004). According to a recent series of surveys conducted at various U.S. cities under the EPA's "Supersite" program, black carbon was often only about 10% of total measured $PM_{2.5}$.[14]

[14] For an overview of the program and initial results see http://www.epa.gov/ttn/amtic/supersites.html

In contrast to total $PM_{2.5}$, diesel PM is composed largely of black carbon. Nonetheless, some diesel PM reduction strategies do not affect black carbon. For instance, diesel oxidation catalysts can reduce diesel PM emissions as a whole by approximately 20 to 40%, yet they do not decrease black carbon emissions (Walker 2004). In addition, while low-sulfur fuel will reduce sulfate emissions, in and of itself low-sulfur fuel will not reduce black carbon. Low-sulfur fuel is important because it *allows* for better technology to reduce black carbon. *See, e.g.* 69 Fed. Reg. 38957, 38995 (June 29, 2004). Yet those reductions can only occur once the technology has been implemented.

In summary, the climate and health impacts of black carbon are undeniable. The main source of black carbon in the U.S. is diesel. The CAFE standards may impact the diesel use if other regulatory mechanisms are not utilized. Thus, the cost-benefit analysis is incomplete because it does not include a monetization of the impacts of black carbon.

VI. The DEIS's cumulative impacts analysis is fundamentally flawed

A cumulative impact is defined under NEPA as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions." 40 C.F.R. § 1508.7.

Global warming is the quintessential cumulative impact – the environmental problem caused by all contributing sources of greenhouse gas emissions together is far greater than that caused by any individual source. The purpose of the cumulative impacts section is to discuss the impact of the NHTSA's rulemaking on the problem overall when considered along with other actions. The NHTSA must place its action in the proper context in order to provide the reader with meaningful information about the impact of its action. For example, the DEIS should answer the question, "to what degree does the NHTSA rulemaking contribute to or hinder the achievement of the greenhouse gas emissions reductions necessary to avoid catastrophic climate change?" The DEIS fails utterly to do so.

The DEIS considered only a single factor in the cumulative impacts section beyond the rulemaking itself – the impact of fuel economy standards for model years 2016-2020. As discussed above, the impact of future fuel economy standards should have been incorporated into the analysis of direct and indirect impacts, as the level chosen by the NHTSA for one year will impact the level achievable in future years. Regardless, however, limiting the cumulative impacts analysis to only considering fuel economy standards for model years 2016-2020 is clearly inadequate on its face to comply with NEPA's requirements.

The DEIS must include a reasonable analysis of the combined impact of the NHTSA's rulemaking on U.S. transportation sector emissions overall, and U.S. emissions overall. For example, is the impact of the current rulemaking sufficient to ensure that the necessary emissions reductions from the U.S. transportation sector overall will be achievable? If the transportation sector does not achieve its "fair share" of necessary emissions reductions, after all, those reductions will have to come from a different sector. While the NHTSA will likely argue that it is difficult to conduct a cumulative impacts analysis for a problem such as greenhouse gas emissions, it is eminently feasible to do so. While the

NHTSA has some discretion in choosing the precise methodology of such an analysis, the agency was clearly not free to omit any such analysis altogether.

Recent scientific evidence indicates that to avoid tipping points and climate catastrophe, it will be necessary to reduce CO_2 emissions to 350 ppm (Hansen et al. 2008). This study uses the most comprehensive analysis to date of both slow and fast feedbacks on climate and reaches the conclusion that global CO_2 concentrations must be capped and reduced to 350 ppm to avoid dangerous and irreversible climate change. Much of the data is based on paleoclimate records, as opposed to computer modeling. The benefit of paleoclimate data is that the changes reflected in proxy measures actually occurred, as opposed to being predictions. The study provides evidence of large changes in sea level on decade time scales as well as past rates of sea level rise in excess of 1 m/century. Thus, a 350 ppm scenario should be included as context for analysis of cumulative impacts. This analysis is entirely possible because MAGICC, the software used to model the climate change impacts of each alternative, already includes various alternative scenarios in which future emissions are controlled so that atmospheric CO_2 concentrations do not exceed values ranging from 350 to 750 ppm.

Moreover, as discussed above, the DEIS is inadequate because it failed to take into account the real world iterative nature of fuel economy improvements, that is, the fact that fuel economy increases today contribute to the capacity for higher levels tomorrow. This DEIS's failure to analyze this crucial issue infected the cumulative impacts analysis as well.

VII. NHTSA must complete an Endangered Species Act Section 7 Consultation to ensure that its action will not jeopardize or adversely modify the critical habitat of any species listed as "threatened" or "endangered"

Congress enacted the Endangered Species Act ("ESA") to conserve endangered and threatened species and the ecosystems upon which they depend. 16 U.S.C. § 1531(b). The Supreme Court's review of the ESA's "language, history, and structure" convinced the Court "beyond a doubt" that "Congress intended endangered species to be afforded the highest of priorities." *Tennessee Valley Authority v. Hill*, 437 U.S. 153, 174 (1978). As the Court found, "the plain intent of Congress in enacting this statute was to halt and reverse the trend toward species extinction, whatever the cost." *Id.* at 184.

Species are added to the lists of endangered and threatened species by the U.S. Fish and Wildlife Service (with jurisdiction over most terrestrial and freshwater species) and the National Marine Fisheries Service (with jurisdiction over most marine species) (collectively, the "Services"). A species is "endangered" if it "is in danger of extinction throughout all or a significant portion of its range." 16 U.S.C. § 1532(6). A species is "threatened" if it "is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." 16 U.S.C. § 1532(20).

Once a species is listed under the ESA, Section 7 requires all federal agencies to "insure" that their actions neither "jeopardize the continued existence" of any listed species nor "result in the destruction or adverse modification" of its "critical habitat." *Id.* at § 1536(a)(2). In addition, the "take" of listed species is generally prohibited. *Id.* at § 1538(a); 50 C.F.R. § 17.31(a). "Take" means "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." 16 U.S.C. § 1532(19). The Services may, however, permit "incidental" take on a case-by-case basis if it finds, among other things, that such take will be minimized and mitigated and that such take will not "appreciably reduce the likelihood of survival and recovery of the species." *Id.* at § 1539(a).

Section 7 consultation is required for "any action [that] may affect listed species or critical habitat." 50 C.F.R. § 402.14. Agency "action" is defined in the ESA's implementing regulations to include "all activities or programs of any kind authorized, funded, or carried out, in whole or in part, by Federal agencies in the United States or upon the high seas. Examples include, but are not limited to: (a) actions intended to conserve listed species or their habitat; (b) the promulgation of regulations; (c) the granting of licenses, contracts, leases, easements, rights-of-way, permits, or grants-in-aid; or (d) actions directly or indirectly causing modifications to the land, water, or air." 50 C.F.R. § 402.02 (emphasis added).

This regulatory definition of "action" clearly encompasses NHTSA's rulemaking, since the emissions from the regulated automobiles unquestionably will cause "modification to the land, water, or air." The U.S. Fish and Wildlife Service's and National Marine Fisheries Service's Consultation Handbook, Procedures for Conducting Consultation and Conference Activities under Section 7 of the Endangered Species Act (March 1998) explains the above terms and definitions. There can also be no question that the enormous volume of direct, indirect, and cumulative emissions from the regulated vehicles "may affect" listed species, and therefore the NHTSA must consult.

The NHTSA's rulemaking will impact species listed as threatened and endangered in several ways, yet the NHTSA has failed to initiate the required Section 7 consultations with the Services on its impact. The NHSTA must initiate and complete the required Section 7 consultations on the rulemaking, or it may be held liable for take of listed species from the impacts of its action, including increased greenhouse gas emissions and other emissions such as NOx.

On May 15, 2008, the U.S. Fish and Wildlife Service listed the polar bear as a threatened species throughout is range due to global warming. Endangered and Threatened Wildlife and Plants, Determination of Threatened Status for the Polar Bear (Ursus maritimus) Throughout its Range, 73 Fed. Reg. 28212-28303 (May 15, 2008). The NHTSA must consult on the impact of its rulemaking, and its proposal to set fuel economy standards far below what is technologically achievable, on the polar bear.[15]

[15] At the same time that the Secretary published the Final Listing Rule he also issued separate regulations, pursuant to Section 4(d) of the ESA, 16 U.S.C. § 1533(d), which authorize the widespread incidental take of polar bears and purport to exempt greenhouse gas pollutants from Section 7's consultation requirements. Endangered and Threatened Wildlife and Plants, Special Rule for the Polar Bear, 73 Fed. Reg. 28306-28318 (May 15, 2008) ("4(d) Rule"). In a section of the 4(d) Rule entitled "Consultation under Section 7 of the ESA," the Secretary alleges that "the best scientific data currently available does not draw a causal connection between GHG emissions resulting from a specific Federal action and effects on listed species or critical habitat by climate change, nor are there sufficient data to establish the required causal connection to the level of reasonable certainty between an action's resulting emissions and effect on species or critical habitat." 73 Fed. Reg. 28306, 28313. NHTSA must not rely on this rule as an excuse to forgo consultation because it is contrary to the best available science and the legal standards for Section 7 consultation. Moreover, exempting greenhouse gas emitting actions from Section 7 cannot be legally accomplished through section 4(d) of ESA. The Center and co-plaintiffs are currently challenging the 4(d) rule in court. See, e.g. Second Amended Complaint in *Center for Biological Diversity v. Kempthorne*, Civ. No. 08-1339 (CW) (N. Dist. Cal.).

On May 9, 2006, the National Marine Fisheries Service listed the staghorn and elkhorn corals as threatened due in part to increasing ocean temperature and ocean acidification due to anthropogenic greenhouse emissions. 71 Fed. Reg. 26852. The NHTSA must consult on the impact of its rulemaking on these coral species. The NHTSA must also consult on the impact of its rulemaking on the polar bear's and the corals' critical habitat, once such habitat is designated.

Global warming was cited by the U.S. Fish and Wildlife Service in its critical habitat rulemakings for the Quino Checkerspot and Bay Checkerspot butterflies. See 73 Fed. Reg. 3328-3373 and 72 Fed. Reg. 48178-48218. The NHTSA must consult on the impact of its rulemaking on these species and their critical habitat.

The NHTSA must not limit its consultation, however, to species like the polar bear, corals, and checkerspot butterflies for which anthropogenic greenhouse emissions were cited as a reason for listing or as an impact in the listing or critical habitat rules. The Center has identified 143 listed species for which a recovery plan has been adopted that specifically identifies climate change or a projected impact of climate change as a direct or indirect threat to the species, as a critical impact to be mitigated, as a critical issue to be monitored, and/or as a component of the recovery criteria. See Exhibit A. This is clear evidence that the NHTSA's rulemaking "may affect" these species. The NHTSA must consult on the impact of its action all listed species which may be affected.

While we are cognizant that federal agencies, for the most part, have not to date been complying with their obligation to consult on the impact of their greenhouse gas emissions on listed species, and therefore there may be some capacity building required for this consultation, this can in no way be used an excuse for continued non-compliance with the law. The direct, indirect, and cumulative impacts of setting fuel economy standards for all cars and light trucks nationally are extraordinarily significant, and therefore a large number of species may be implicated. Where, as here, the NHTSA's rulemaking is national in scope, the NHTSA should conduct a nationally focused consultation. Again, the NHTSA must not attempt to use the large scale of its action as an excuse for ignoring its environmental review duties, since the highly significant nature of the action only makes it more important to thoroughly review its impacts under all applicable laws. Nor can the mere fact that a large geographical area or large number of species be used an excuse for inaction. See, e.g., *Wash. Toxics Coalition v. EPA*, 413 F.3d 1024 (9th Cir. Wash. 2005) (upholding order requiring the EPA to consult on the impact of 54 pesticide ingredients on 25 species of fish.). If anything, a nationally focused consultation will provide the opportunity to most efficiently analyze the impact of the rulemaking on species and groups of species.

The rulemaking will impact listed species in ways beyond global warming and ocean acidification. For example, vehicles are a primary source of excess nitrogen in the environment. Excess nitrogen contributes to major environmental problems including reduced water quality, eutrophication of estuaries, nitrate-induced toxic effects on freshwater biota, changes in plant community composition, disruptions in nutrient cycling, and increased emissions from soil of nitrogenous greenhouse gases (Fenn et al. 2003). Nitrogen deposition therefore impacts species listed under the Endangered Species Act in a number of ways.

Nitrogen deposition has contributed to the severe decline of the threatened bay checkerspot butterfly, endemic to the San Francisco Bay Area. (Fenn et al. 2003). The bay checkerspot butterfly is restricted to outcrops of serpentine rock which are low in nitrogen and support a diverse native grassland with more than 100 species of forbs and grasses, including the butterfly's host plants. (Fenn et al. 2003). Nitrogen deposition in the soil creates a more hospitable environment for non-native grasses which crowd out the butterfly's host primary host plant, *Plantago erecta.* (Fenn et al. 2003). Nitrogen deposition and increasing non-native grass invasion has similarly acted in concert with global warming and drought to extirpate the Quino checkerspot butterfly in much of its range in southern California. (Fenn et al. 2003).

Nitrogen deposition also contributes to type conversion of Southern California's coastal sage scrub vegetation community to non-native grasslands, threatening a host of species listed under the Endangered Species Act including the California gnatcatcher (Fenn et al. 2003). Nitrogen deposition is a problem in desert ecosystems, as well. The threatened desert tortoise is also impacted by the increased spread of non-native plants with lower nutritional value for the species (Fenn et al. 2003). Protection and recovery efforts for many threatened and endangered species may therefore not succeed without regional and national level policies to reduce air pollution (Fenn et al. 2003).

The NHTSA must complete the required consultations on the impact of its rulemaking on species listed as threatened and endangered under the Endangered Species Act. The NHTSA remedy its violations of EPCA and NEPA, discussed throughout, which mask the true impact of the rulemaking, prior to completing the consultations so that the fundamental flaws in the EPCA and NEPA analyses do not infect the ESA analysis.

VIII. The NHTSA's Inadequate Analysis of its Unlawfully Low Fuel Economy Proposal is Reflective of the Current Administration's Opposition to the Regulation of Greenhouse Gas Emissions

The countless flaws and errors in the NHTSA's analysis are gravely troubling even when viewed in isolation, but are even more so when viewed in conjunction with other ongoing regulatory processes. The Bush administration has opposed all regulation of greenhouse gas emissions, and has resorted to extraordinary and illegal actions in order to block any such regulation. A brief review of other ongoing processes reveals this administration's truly unprecedented contempt for the law, and provides insight into how and why NHTSA released such a flawed proposal and DEIS.

In 2000, George W. Bush campaigned on a pledge to regulate carbon dioxide emissions as central component of his energy policy.[16] His administration's relentless opposition to such regulation, however, began immediately after he took office. In a March 13, 2001 letter, Bush proclaimed: "I do not believe, however, that the government should impose on power plants mandatory emissions reductions for carbon dioxide, which is not a 'pollutant' under the Clean Air Act."[17] Vice President Cheney said of Bush's campaign pledge, "It was a mistake because we aren't in a position today to...cap

[16] For example, on Sept. 29, 2000, while campaigning in Saginaw, MI, Bush said: "We will require all power plants to meet clean-air standards in order to reduce emissions of carbon dioxide within a reasonable period of time." http://thinkprogress.org/2006/07/07/co2-pledge/.
[17] http://www.whitehouse.gov/news/releases/2001/03/20010314.html.

emissions." That flip-flop set the stage for eight years of stubborn opposition to common sense and legally mandated controls for greenhouse gas emissions, as well as an ever expanding constellation of scandals.

The central scandal of the climate change arena is the administration's refusal to regulate greenhouse gas emissions pursuant to Section 202 of the Clean Air Act. The EPA's rejection of a petition from the International Center for Technology Assessment and others to regulate greenhouse gas emissions from automobiles caused years of delay but led ultimately to the Supreme Court's April 2007 ruling in *Massachusetts v. EPA*. In that decision, the high court ruled that carbon dioxide is a "pollutant" and ordered the EPA to determine whether it can "reasonably be anticipated to endanger public health or welfare." An affirmative answer, known as the "endangerment finding," would require regulation under the Clean Air Act.

The administration has thus far refused to release such a finding. Following the Supreme Court's ruling, the EPA produced a draft endangerment finding that concluded, according to notes produced by Senator Barbara Boxer's staff who viewed the document, that "elevated levels of [greenhouse gas] concentrations may reasonably be anticipated to endanger public welfare." (Senate EPW Staff Report 2008). While such a finding would have led to regulation, it is a vast understatement and addresses only the public welfare prong while omitting the public health prong.

Former EPA Associate Deputy Administrator Jason Burnett told Congress that EPA staff had hoped to win White House approval of the agency's finding by omitting discussion of health impacts, which the EPA has elsewhere admitted include increased heat-related illness and death, increased heart and lung illness from increased ozone levels associated with higher temperatures, increased spread of air and water-borne pathogens, and other impacts (Burnett Letter July 6, 2008; Burnett EPW Testimony July 22, 2008).

This omission is evidence of one of the most insidious results of the crushing political interference to which this administration has subjected virtually every major regulatory process: self-censorship among government employees. Many scientists and regulators now walk a tortured path between what a statute requires and what they think the administration might approve.

Not surprisingly, the appeasement approach didn't work with regard to regulation of greenhouse gas emissions from vehicles under the CAA. When the EPA transmitted the draft endangerment finding to the White House on December 5, 2007, the administration refused to "open the attachment," ultimately leading to Burnett's resignation. With the December 5 draft unopened, the EPA instead converted the endangerment finding into a bizarre advance notice of proposed rulemaking (73 Fed. Reg. 44354. "ANPR"). Even the ANPR, which is nothing more than a stall tactic to further delay regulation, was subjected to intense political manipulation. Between a May 30, 2008 draft and publication in the Federal Register, EPA's modeling inputs were changed in order to understate the benefits and overstate the costs of regulating greenhouse pollutants. Cf. May 30, 2008 Draft ANPR draft to 73 Fed. Reg. 44354.

EPA Administrator Stephen Johnson's announcement of the ANPR could easily have been lifted straight from a George Orwell novel. Johnson's statement, "I believe … the Clean Air Act, an outdated law originally enacted to control regional pollutants that cause direct health effects, is ill-suited for the task of regulating global greenhouse gases," perfectly encapsulates this administration's contempt for the law, science, and "reality-based" governance.

The reality is that the Clean Air Act is our most successful law for protecting the air we breathe and, consequently, our health and welfare. Since the law's enactment forty years ago, emissions of toxic lead have dropped 98 percent, emissions of sulfur dioxide, a major component of acid rain, have fallen by 35 percent, and emissions of carbon monoxide – a once-common, and deadly, pollutant in the air above most American cities – have been reduced by 32 percent even though driving has increased. Moreover, the economic value of the air quality improvements has been many times greater than the cost of the regulations.

The Clean Air Act has ready-made provisions to regulate greenhouse gas emissions not only from automobiles, but also from power plants, ships, airplanes, offroad engines, and other sources. It is a senseless tragedy that Americans have been deprived of the benefits of applying the Clean Air Act's successful regulatory strategies to greenhouse pollutants while emissions from automobiles, ships, airplanes and other sources continue unabated.

The administration's opposition to regulation was driven home with letters from agency heads placed at the beginning of the ANPR. These letters show the raw politics that pervaded the administrative process. A letter signed by Mary E. Peters, U.S. Department of Transportation Secretary and three other agency heads asserts that it is simply not "desirable" to regulate greenhouse gas emissions. 73 Fed. Reg. 44362. Moreover, the letter asserts (incorrectly) that regulation could not possibly do any good:

> Petroleum product prices have doubled in two years, equivalent to a carbon tax of $200 per metric ton, far in excess of the cost of any previously contemplated climate change measure. Operators are searching for every possible operating economy, and capital equipment manufacturers are fully aware that fuel efficiency is a critical selling point for new aircraft, vehicles, and engines. At this point, regulations could provide no more powerful incentive for commercial operators than that already provided by fuel prices.

Id.

Finally, the agency heads make the breathtaking assertion that "the United States can only effectively address GHG emissions and global climate change in coordination with other countries, and by addressing how to regulate GHG emissions while considering the effect of doing so on the Nation's energy and economic security." 73 Fed. Reg. 44365. It is astounding that after eight years of the Bush State Department relentlessly blocking even any discussion of, let alone movement towards, mandatory international limits on greenhouse pollutants through the U.N. Framework Convention on Climate Change, that the any political appointee would have the gall to assert that domestic action cannot proceed prior to international action. It is nothing short of insane for the U.S. Transportation Secretary, while asserting that the "maximum feasible" fuel economy that can be achieved in the U.S. in 2015 is less than the current standard in China, to simultaneously assert that it is lack of international progress that is holding the U.S. back.

While the administration has refused to regulate greenhouse pollutants pursuant to Section 202 of the Clean Air Act, it has also blocked California's efforts to implement its Clean Vehicle Law (AB 1493, 2002) by refusing to issue the required waiver under the Clean Air Act. Administrator Johnson announced his decision to deny the waiver on December 19, 2008. It later emerged that Johnson had overruled the explicit conclusions of his professional staff (House Oversight Committee Memo May 19, 2008). Administrator Johnson then apparently lied to Congress about the process, prompting Congressional calls for an investigation by Attorney General Michael Mukasey and calls for his resignation. (Senators Boxer et al. letter July 29, 2008; Senate EPW Call for Resignation July 29, 2008).

And while the administration continues to assert, incorrectly, that regulation of emissions from automobiles is equivalent to the regulation of fuel economy, the administration has, of course, just proposed the current set of pathetically inadequate fuel economy standards, despite the Ninth Circuits invalidation of the last set of inadequate standards in *Center for Biological Diversity* less than 9 months ago.

The administration has continued to block progress on implementing solutions to global warming at every level, and has resorted to a level of censorship and suppression of science never before seen in this country. Well publicized examples include attempts at censoring the nation's top climate scientist, Dr. James Hansen, at NASA (Revkin 2006), suppression of the scientific assessment of climate change impacts in the United States required by the Global Change Research Act of 1990 (*see Center for Biological Diversity v. Brennan*, No. C-06-7062 SBA (N.D. Cal. August 21, 2007), extensive editing of climate change assessment documents by Philip Cooney (Revkin 2005) and political interference in the Endangered Species Act listing process for the polar bear.

Political interference in government climate science has become pervasive in the past five years. As the Union of Concerned Scientists found:

> In the summer of 2006, the Union of Concerned Scientists distributed surveys to more than 1,600 climate scientists working at seven federal agencies and the independent National Center for Atmospheric Research (NCAR), asking for information about the state of climate research at federal agencies. Scientists' responses indicated a high regard for the quality and integrity of federal climate research itself, but also identified broad and substantial interference in their work.
>
> The reality of global warming, including the role of heat-trapping gases from human activities in driving climate change, has been repeatedly affirmed by scientific experts. Every day the government stifles climate science is a day we fail to protect future generations from the consequences of global warming. It is crucial that climate scientists be allowed to accurately inform government decisions. For this to occur, the federal government must pursue reforms that prohibit political interference and misrepresentation of federal climate science research, and affirm the right of scientists to communicate freely with the media and the public....

I. Political Interference with Climate Science

Large numbers of federal climate scientists reported various types of interference, both subtle and explicit:

- 73 percent of all respondents* perceived inappropriate interference with climate science research in the past five years.
- 58 percent of all respondents personally experienced interference with climate science research in the past five years. This number increased to 78 percent among scientists whose work always or frequently touches upon sensitive or controversial topics. In contrast, only 22 percent of NCAR scientists personally experienced interference with climate science research.
- Nearly half of all respondents (46 percent) perceived or personally experienced pressure to eliminate the words "climate change," "global warming," or other similar terms from a variety of communications. This number increased to nearly three in five (58 percent) among respondents from the National Oceanic and Atmospheric Administration (NOAA).
- 46 percent of all respondents perceived or personally experienced new or unusual administrative requirements that impair climate related work.

II. Scientific Findings Misrepresented

Federal climate scientists reported that their research findings have been changed by non-scientists in ways that compromise accuracy:

- Two in five respondents (43 percent) perceived or personally experienced changes or edits to documents during review processes that changed the meaning of scientific findings.
- 25 percent perceived or personally experienced situations in which scientists have actively objected to, resigned from, or removed themselves from a project because of pressure to change scientific findings.
- 37 percent of respondents perceived or personally experienced instances in which their agency misrepresented scientists' findings.

III. Barriers to Communication

Agency scientists are not free to communicate their research findings to the media or the public:

- 52 percent of respondents said their agency's public affairs officials always or frequently monitor scientists' communications with the media. In contrast, only seven percent of NCAR respondents reported that same level of monitoring.
- Two in five respondents (39 percent) have perceived or personally experienced "fear of retaliation for openly expressing concerns about climate change outside their agency."
- 38 percent of respondents perceived or personally experienced "disappearance or unusual delay of websites, reports, or other science-based materials relating to climate."

- A majority of NASA respondents (61 percent) agreed with the statement, "Recent changes to policies pertaining to scientific openness at my agency have improved the environment for climate research," in sharp contrast to the 12 percent of non-NASA respondents who agreed with the statement. The high percentage among NASA respondents is most likely the result of a recent policy implemented at the agency that affirmed that the role of public affairs officers was not "to alter, filter or adjust engineering or scientific material produced by NASA's technical staff."

IV. Climate Scientists are Disheartened

While a large majority of respondents (88 percent) agreed with the statement, "U.S. federal government climate research is of generally excellent quality," respondents reported decreasing job satisfaction and a worsening environment for climate science in federal agencies:

- Two-thirds of respondents said that today's environment for federal government climate research is worse compared to five years ago (67 percent) and 10 years ago (64 percent). Among scientists at NASA, these numbers were nearly four in five (79 percent and 77 percent, respectively).
- 45 percent of all respondents said that their personal job satisfaction has decreased over the past few years. At NASA, three in five (61 percent) reported decreased job satisfaction.
- More than a third of respondents from NASA, and more than one in five (22 percent) of all respondents, reported that morale in their office was "poor" or "extremely poor." Among NCAR respondents, only seven percent reported such low levels of morale.
- Insufficient resources are a source of concern among respondents. More than half (53 percent) disagreed with the statement, "The U.S. government has done a good job funding climate research."

Survey Demographics

Surveys were sent to 1,630 scientists at the National Aeronautics and Space Administration, National Oceanic and Atmospheric Administration, U.S. Environmental Protection Agency, U.S. Department of Energy, U.S. Department of Defense, U.S. Geological Survey, U.S. Department of Agriculture, and the independent (non-federal) National Center for Atmospheric Research (NCAR).

Responses came from 279 federal scientists and 29 NCAR scientists. One hundred forty-four scientists provided narrative responses. The response rate (19 percent) was fairly consistent across agencies. Eighty percent of the scientists who responded had earned a Ph.D. and 40 percent had completed some post-doctoral research work. A significant number of respondents (44 percent) had been with their agency for more than 15 years, and more than half had been there for more than 10 years.

(UCS 2006[18]; see also Oversight Committee 2008).

The administration has also repeatedly touted the discredited statements of a small number of pseudo-scientists funded by industry groups in order to sow doubt in the minds of Americans about climate change by manipulating the media (UCS 2007). This campaign has been extremely successful. Oreskes (2004) looked at 928 articles in the peer reviewed scientific journals dealing with climate change, and found 0% in doubt as to the cause of global warming (See also Oreskes 2006). Boykoff and Boykoff (2004) looked at 636 articles in the "prestige media" (NYT, WaPo, LA Times, WSJ) and found 53% of articles included a statement of doubt as to the cause of global warming.

It is readily apparent that the NHTSA's fuel economy proposal and DEIS violate the EPCA and NEPA. Yet when viewed in light of the administration's opposition to any regulation of greenhouse gas emissions and pervasive use of censorship and political interference to enforce its policies, the NHTSA's legal violations are all the more disturbing.

X. Conclusion

Setting fuel economy standards for all cars and light trucks nationally is one of the single most important actions that the government can take to reduce greenhouse emissions. The NHTSA should correct the flaws identified above in the EPCA and NEPA analyses, and promptly propose and then finalize new fuel economy levels which actually achieve the "maximum feasible" level.

Thank you for the opportunity to submit these comments. Please contact Brian Nowicki at (916) 201-6938 if you have any questions or concerns.

Yours Sincerely,

Kassie Siegel
Climate, Air, and Energy Program Director

Exhibit A: Climate Change Impacts to Endangered Species Act Listed Species Documented in Recovery Plans

The following is a list of 143 species (including subspecies and distinct population segments) listed as Threatened or Endangered under the federal Endangered Species Act, for which a Recovery Plan has been adopted that specifically identifies climate change or a projected impact of climate change as a direct or indirect threat to the species, a critical impact to be mitigated, a critical issue to be monitored, and/or a component of the recovery criteria.

For each species, some or all of the relevant text is excised and cited to the page number in the Recovery Plan. The vast majority of these Recovery Plans is available on the public websites of the U.S. Fish and Wildlife Service or National Marine Fisheries Service, and the direct link is provided. A small number may be available only in hard copy.

This list is not necessarily all-inclusive, due to the difficulty of obtaining some recovery plans, and the search includes only plans adopted before May 2008.

Steller sea-lion (eastern DPS) *Eumetopias jubatus* (Eastern DPS)
Recovery plan for the Steller sea lion, eastern and western distinct population segments (Eumetopias jubatus) revision. 2008
www.nmfs.noaa.gov/pr/pdfs/recovery/stellersealion.pdf

(N)o threats to continued recovery were identified for the eastern DPS...However, concerns exist regarding global climate change and the potential for the southern part of the range (i.e., California) to be adversely affected. Future monitoring should target this southern portion of the range. (XIII)

If nutritional stress is being caused by an anthropogenic factor, it is probably linked to removal of important sea lion prey species by commercial fisheries (Atkinson et al. in press), although anthropogenic effects on climate could potentially have increasingly important impacts on sea lion prey in the coming decades. However, environmental features, such as oceanographic regime shifts, could also affect the relative abundance and distributions of key prey. (I-33)

Global climate change. Characteristics of recent climate change in the North Pacific were discussed in detail in Section III.H. In that section it was noted that some features of the ecosystems of the Pacific Northwest (California to British Columbia and southeast Alaska) and the northern North Pacific (Gulf of Alaska and Bering Sea) are out of phase, including recruitment of Pacific salmon and some groundfish stocks (Hollowed and Wooster 1992, Hare et al. 1999), and zooplankton biomass (Brodeur et al. 1996, Roemmich and McGowan 1995). Such variability may be due to patterns of transport in the North Pacific Current when it bifurcates off the coast of British Columbia to form the northward-flowing Alaska Current and the southward-flowing California Current (Wickett 1966, Hollowed and Wooster 1992). How such variations may affect organisms at the top of the trophic system, such as Steller sea lions, is unknown.

Sydeman and Allen (1999) investigated correlations between oceanographic features and population dynamics of central California pinnipeds Multiple regression analysis of sea surface temperatures and upwelling index versus abundance found no relationship for Steller sea lions. Additionally, despite documented shifts in climate and oceanographic processes that may have affected productivity at multiple trophic levels, California sea lion pup production along the US west coast has increased at approximately 5% per year since 1975 and the eastern DPS of Steller sea lion has also increased at approximately 3%/year with no apparent variability associated with climatic variation. Thus, although there have been documented and perhaps more frequent oceanographic and climatic changes, the population of Steller sea lions has not responded negatively from a Steller Sea Lion Recovery Plan population perspective. The most evident change is that all of the new rookeries in the eastern DPS have been established in Alaska at the northern end of the range suggesting a population shift to the north. (VI-5-6)

(N)o threats to continued recovery were identified for the eastern DPS...However, concerns exist regarding global climate change and the potential for the southern part of the range (i.e., California) to be adversely affected. Future monitoring should target this southern portion of the range. (XIII)

Steller sea-lion (Western DPS) *Eumetopias jubatus* (Western DPS)
Revised Steller Sea Lion Recovery Plan, Eastern and Western Distinct Population Segments (Eumetopias jubatus) 2008
www.nmfs.noaa.gov/pr/pdfs/recovery/stellersealion.pdf

If nutritional stress is being caused by an anthropogenic factor, it is probably linked to removal of important sea lion prey species by commercial fisheries (Atkinson et al. in press), although anthropogenic effects on climate could potentially have increasingly important impacts on sea lion prey in the coming decades. However, environmental features, such as oceanographic regime shifts, could also affect the relative abundance and distributions of key prey. (I-33)

The two bottom-up factors hypothesized to have contributed most to the decline are reductions in prey biomass and quality resulting in nutritional stress (proximate cause) that subsequently decreases vital rates (Trites et al. 2006a). However, there are two hypotheses about the ultimate causes of nutritional stress. In one, nutritional stress stems from climate induced changes in the species composition, distribution or nutritional quality of the sea lion prey community (see review by Trites and Donnelly 2003, Trites et al. 2006a, and Trites et al. 2007b). In the other, fishery-induced reductions in localized or overall prey abundance cause nutritional stress (Braham et al. 1980, NMFS 1998a, 2000). Both climate shift and fisheries induced changes in prey communities may have affected the condition of Steller sea lions over the last 40 years, but the relative importance of each is a matter of considerable debate. (III-3)

Global Climate Change. Climate change has received considerable attention in recent years, with growing concerns about global warming and the recognition of natural climatic oscillations on varying time scales. Global air and ocean temperatures during this century and before are warming (IPCC 2007, see http://www.ipcc.ch), and evidence suggests that the productivity of the North Pacific is affected by changes in the environment (Quinn and Niebauer 1995, Mackas et al. 1998).

Increases in global temperatures are expected to have profound impacts on arctic and sub-arctic ecosystems, and some of these impacts have been documented over the last several decades. Specifically, (1) winter temperatures in Alaska and western Canada have increased as much as 3-4 °C over the past half century, (2) precipitation, mostly in the form of rain, has increased primarily in winter resulting in faster snowmelt, (3) sea ice extent has decreased about 8% over the past 30 years, with a loss of 15 to 20% of the late-summer ice coverage in the arctic, and (4) glacial retreat, particularly in Alaska, has accelerated contributing to sea level rise (ACIA 2004). These impacts, and others, are projected to accelerate during this century.

The effects of these changes to the marine ecosystems of the Bering Sea, Aleutian Islands, and the Gulf of Alaska, and how they may specifically affect Steller sea lions are uncertain. Warmer waters could favor productivity of certain species of forage fish, but the impact on recruitment dynamics of fish of importance to sea lions is unpredictable. Recruitment of large year-classes of gadids (e.g., pollock) and herring has occurred more often in warm than cool years, while the distribution (with respect to foraging sea lions) and recruitment of other fish (e.g., osmerids) could be negatively affected. Whether these patterns will continue as overall temperatures increase is uncertain, as are the effects on the duration and strength of atmospheric and oceanographic regimes (Trenburth and Hurrell 1994, Hare and Mantua 2000).

Climate-driven changes in productivity and community structure due to warming oceans may already be underway in the northern portion of the Bering Sea and Bering Strait, where sea ice plays a major role in structuring the food web and the ecosystem is particularly vulnerable to rapid system reorganization under global warming. Reduced seasonal sea ice cover, changing hydrographic conditions, and reduced primary production in the northern Bering Sea may be associated with apparent declines in ice-associated benthic species of mollusks and amphipods since the 1990s (Grebmeier et al. 2006). Benthic-feeding walrus, bearded seals, gray whales and diving sea-ducks such as Spectacled eider are all threatened by these changes, as are Arctic Native communities whose traditional subsistence culture has relied on these iceassociated mammals and birds for thousands of years. This ecosystem has short, simplified food chains; thus the potential for trophic cascades is higher. Warming seawater in the north could expand the range of groundfish from the south, putting more pressure on the benthic prey base. The northern Bering Sea may be poised for the sort of trophic cascade and system reorganization anticipated by the U.S. GLOBEC (Global Ocean Ecosystems) research program as a consequence of global warming at high latitudes (Grebmeier et al. 2006).

Warmer temperatures could shift the distribution of sea lions northward. The eastern DPS increased in size at a rate of approximately 3% per year from the early 1980s through 2004, despite a decline in the size of the breeding population at the southern extent of its range in California. All of the increase in the eastern DPS occurred north of California, and new rookeries established in the 1990s (White Sisters and Hazy Island) were near its northernmost extent in southeast Alaska.

As temperatures warm and global ice coverage decreases, sea levels will rise. This will directly affect terrestrial rookery and haulout sites currently used by Steller sea lions as well as those that may be used by a recovering population. Presumably, sea lions using terrestrial sites will simply move upslope as sea levels rise, assuming that the terrain at the site is suitable. However, sites on some islands with low relief (e.g., Agligadak Island) may be submerged. The net effect of a rise in sea level on overall terrestrial sea lion habitat amount or availability is uncertain, but at the projected rate it is unlikely to have a significant effect for many years.

Fluctuations or cycles in physical and biological characteristics of marine ecosystems may not necessarily affect higher trophic levels because of strategies for survival they have evolved to buffer them against environmental uncertainty. Based on their analyses of possible causes of the sea lion decline, Pascual and Adkison (1994) concluded that environmental cycles were unlikely to have caused declines of the magnitude and duration observed. Shima et al. (2000) did a comparative analysis of population dynamics of four species of pinnipeds in similar variable environments (Steller sea lions in the Gulf of Alaska, Cape fur seals in the Benguela Current, harp seals in the Barents Sea, and California sea lions in the California Current) and found a major decline only for Gulf of Alaska Steller sea lions. They concluded that the success of the other populations suggests that pinnipeds in general have the ability to adapt to environmentally driven changes in prey resources, and that other factors were involved in the decline of Steller sea lions.

Data gaps… More research is necessary to describe linkages between changes in the environment and the dynamics of apex predators such as Steller sea lions. Distinguishing between anthropogenic and environmentally-driven changes in the abundance and distribution of prey resources has eluded scientists and managers, but is necessary in order to understand the forces underlying change in population size and demographics. Furthermore, the direct effects of temperature increases on sea lion metabolic rates, foraging efficiencies, and disease transmission are unknown. (III-31-32).

The hypotheses proposed to explain the decline of the western stock fall into two categories. The first category, the bottom-up hypotheses, includes potential causes that would affect the physical condition of sea lions such as large-scale fishery removals that reduce the availability or quality of prey species, a climate/regime shift in the late 1970s that changed the abundance or distribution of prey species, nonlethal disease that reduced the foraging efficiency of sea lions, and pollutants concentrated through the food web that contaminated fish eaten by sea lions, possibly reducing their fecundity or increasing mortality. (IV-2)

In the last several decades, several new threats have developed; i.e., contaminants, global climate change, and both top-down (e.g., incidental take) and bottom-up (reduced prey biomass and quality) effects of fisheries. (IV-10)

Biological concerns: In general, NMFS expects to see that both juvenile survival and pup production (natality) have increased to the point that the population is not only able to sustain itself, but is able to grow at a modest rate. One feature of the North Pacific, decadal scale climate change, appears to have ecosystem-scale ramifications and may potentially influence the recovery of Steller sea lions. (V-16-17)

Design and implement an adaptive management program for fisheries, climate change, and predation. The mechanisms by which different threats affect sea lions can be similar, as are the responses that sea lions exhibit to these different threats. This represents a fundamental difficulty in identifying which threats are impeding recovery and which mitigation measures would be effective. A properly designed and implemented adaptive management program is needed to assess the relative impact of fisheries, climate change, and predation (Bowen et al. 2001, NRC 2003). (V-43)

To provide assurance that reclassification is warranted for the western DPS of Steller sea lion, several natural and anthropogenic threats to its continued existence including subsistence harvest, pollution, toxins, and management should be reduced as specified under this factor:...3. The influence of global climate change and oceanographic variability is examined, including in combination with other human influenced factors, and is determined unlikely to limit recovery. (V-20)

Nesogenes rotensis
Recovery plan for two plants from Rota 2007
http://ecos.fws.gov/docs/recovery_plans/2007/070503.pdf

There is some evidence that the frequency of severe storms (estimated gusts exceeding 160 kilometers (100 miles) per hour) is increasing in the Mariana Islands. With reference to Guam, the historical record shows increasing numbers of mild (estimated gusts in the range of 80 to 160 kilometers (50 to 100 miles) per hour) and severe storms over the last three centuries, as well as in just the last decade. While some underreporting of storms may have occurred in prior centuries, even mild storms were noticed in the colonial era because they destroyed the relatively flimsy structures used for early housing. Furthermore, these data are consistent with trends expected on the basis of increasing sea surface temperatures that have been documented in recent years (e. g. , Strong et al. 1998; U. S. Department of State 1999). The two populations of N. rotensis are especially vulnerable to the extreme impact of typhoons, storm surge, and high surf because their open scrubland habitats are located in coastal areas.

http://ecos.fws.gov/docs/recovery_plan/071119.pdfhttp://ecos.fws.gov/docs/recovery_plan/071119.pdf

Disease...Hudson et al. (2006) speculated that increased temperatures and climatic disruption brought about by global warming will result in increased frequency and intensity of outbreaks of some parasite populations like Trichostrongylus tenuis. (40)

Chinook salmon (Puget Sound DPS) *Oncorhynchus tshawytscha* pop. 15
Puget Sound Salmon Recovery Plan 2007

...Puget Sound Chinook and Coastal-Puget Sound bull trout are affected by regional and global factors such as climate change and fluctuating ocean conditions. Although it is clear that these factors directly affect salmon and bull trout, scientists are only beginning to unravel the secrets of how these processes impact the food chain, precipitation and snowpack, and other habitat features. Temperature conditions and ocean cycles affect migration and the abundance of predators, and are essential in the production of the minute organisms that provide the food supply for salmon and bull trout to grow and flourish. (122)

Climate Change in the Pacific Northwest. Data collected during the 20th century revealed widespread increases in average annual temperature and precipitation, and decreases in the April 1 snow water equivalent. Snow water equivalent is a common measurement for the amount of water contained in snowpack and is an important indicator for forecasting summer water supplies. 1990-2000 was the warmest decade on record, and was warmer than any other decade by 0.9oF (CIG, 2004). Long term models for climate change in the 21st century show evidence of trends including, region-wide warming, increased precipitation, declining snowpack, earlier spring runoff, and declining trends in summer streamflow. (CIG, 2004) Most of the models predict warmer, wetter winters and warmer, drier summers for the Pacific Northwest. Figure 3.33 contains a summary of the observed and projected impacts of climate change relevant to salmon and bull trout populations.

Salmon and bull trout have lived in the Pacific Northwest for millions of years. As different species and populations of salmon have developed over time, they have acquired specific behaviors for their migration, rearing and spawning life cycles that are attuned to temperature and streamflow. This complex life cycle makes it difficult to predict how they will react to climate changes, and their response will also vary depending on the habitat conditions in a particular river system and estuary. Changes in temperatures away from optimal conditions can influence salmon and bull trout in each of their life stages. Even a small increase in temperature can change migration timing, reduce growth, reduce the supply of available oxygen in the water, and increase the susceptibility of fish to toxins, parasites and disease. The increase in stream temperatures can also contribute to a reduction in the preferred species of insects that are used for food (NWF, 2005). Earlier spring runoff and lower summer flows may make it difficult for returning adult salmon to negotiate obstacles. Excessively high levels of winter flooding can scour eggs from their nests in the streambeds and increase mortalities among overwintering juvenile salmon and bull trout.

Adaptive strategies to cope with the projected changes largely focus on the need to maintain salmon and bull trout populations through conservation and restoration of freshwater and estuarine habitat. Additionally, it has been recommended that harvest and hatchery managers pay particular attention to the time lag associated with impacts of natural variability in one season on the viability of populations in successive seasons. For example, productivity may decline following drought conditions and should be factored into hatchery production targets and harvest regimes; similar issues are already being considered during technical planning forums for harvest.

The predicted increased winter flooding, decreased summer and fall streamflows, and elevated warm season temperatures in the streams and estuaries are likely to further degrade conditions for salmon that are already stressed from habitat degradation. Although the impacts of global climate change are less clear in the ocean environment, early modeling efforts suggest that, warmer temperatures are likely to increase ocean stratification, which in the past has coincided with relatively poor ocean habitat for most Pacific Northwest salmon, herring, anchovies, and smelt populations. (CIG, 2004) (122-123)

Increased frequency and magnitude of high stream flows is due in part to the loss of forest cover from timber harvesting and the routing of surface runoff from forest roads into streams; thus the naturally challenging hydrology of the basin is exacerbated. High flows have contributed to scouring upstream salmon spawning beds, and smothering downstream spawning beds with high sediment levels. Peak flows may also flush juvenile salmon out of normally slower moving reaches of the river that are used for rearing habitat. In the future, climate change may lead to wetter winters and drier summers, aggravating the current flow challenges. (196)

Rate, timing, quantity and quality of water will potentially be negatively impacted due to population growth and increased impervious surfaces, cumulative impact of forest harvest and/or climate change. The degree to which cumulative impacts of forest harvest will impact hydrologic function is unknown. (197)

During the May 2005 review of watershed chapters and regional plan elements, the Technical Recovery Team and an interagency committee identified a preliminary list of issues that have high uncertainty and need to be incorporated into the adaptive management plan:...The potential impacts of climate change on salmon recovery. Climate change, both natural and induced, could have significant effects on Chinook salmon and other salmonids in the Puget Sound region and beyond. Possible effects include alteration of the hydrologic cycle resulting in changes in low and high flow patterns, changes to habitat forming processes, changes in terrestrial and riparian vegetation that affect habitat forming processes, changes in erosion patterns, and impacts to water quality. Significant research on this topic is being conducted in the region, however none of the watershed plans have proposed means of monitoring climate change or its impacts. This is a significant uncertainty in the Puget Sound Recovery Plan and should be addressed through the detailed watershed and regional adaptive management plan. (454-455)

Although the residents of Puget Sound may not have direct influence over climate change, ocean conditions or marine mammal populations, several of the adaptive strategies suggested by the scientific community stress the need to ensure that local habitat conditions are protected and restored as a buffer against the coming changes, and that harvest and hatchery management consider these long term factors in their decision-making. (122)

Chinook salmon (Upper Columbia River spring run DPS) *Oncorhynchus tshawytscha* pop. 12
Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan 2007
http://www.nmfs.noaa.gov/pr/pdfs/recovery/proposed_uppercolumbiasalmon.pdf

The potential impacts of global climate change are recognized at national and international levels (Scott and Counts 1990; Beamish 1995; McGinn 2002). Many climate models project changes in regional snowpack and stream flows with global climate change. The effects of these changes could have significant effects on the success of recovery actions and the status of listed fish populations in the Upper Columbia Basin. The risks of global climate change are potentially great for Upper Columbia stocks because of the sensitivity of salmon stocks to climate-related shifts in the position of the sub-arctic boundary, the strength of the California Current, the intensity of coastal upwelling, and the frequency and intensity of El Nino events (NPCC 2004). Bull trout are particularly sensitive to water temperatures and it is uncertain how global climate change will affect their habitat. More research is needed to address the effects of climate change on ocean circulation patterns, freshwater habitat, and salmon and trout productivity. (105)

Chiricahua leopard frog *Rana chiricahuensis*
Chiricahua Leopard Frog (Rana chiricahuensis) Recovery Plan 2007
http://www.fws.gov/southwest/es/arizona/Documents/SpeciesDocs/CLF/Final_CLF_Plan.pdf

Climate change is listed among threats/factors in decline. (iv, 21, 27, 34, B-74, C-8)

Global Climate Change, Pesticides and Other Non-Mining-related Contaminants, UV-B Radiation, and Other Stressors (Listing Factor A, D, E) Predation by non-native species, chytridiomycosis, habitat loss and degradation, and other factors discussed have been documented as the most likely causes of population decline and extirpation of the Chiricahua leopard frog. However, populations sometimes disappear from habitats in which no changes or deterioration of habitat are apparent, no non-native predators have been detected, and for which there is no evidence of disease. In these and potentially other cases, important stressors other than those just discussed may be adversely affecting Chiricahua leopard frog populations. These factors may include climate change or climatic extremes (Dimmitt 1979, Fellers and Drost 1993, Pounds et al. 1999, Alexander and Eischeid 2001); transport (sometimes over long distances) and deposition of contaminants, dust, gases (Stallard 2001), and pesticides (Lips 1998, Cowman et al. 2001, Davidson et al. 2002); increased levels of ultraviolet-B radiation and interactions with pathogens, particularly a water mold (Saprolegnia ferax) (Blaustein et al. 1994, Keisecker and Blaustein 1995); acid rain (Blanchard and Stromberg 1987, Vatnick et al. 1999); and over-collection (Jennings and Hayes 1985). Globally, the 22 hottest years on record have occurred since 1980, the 10 hottest years have all occurred since 1990, and 2005 was the hottest year in recorded history. The Intergovernmental Panel on Climate Change (2001) found that most of the observed warming over the last 50 years is likely attributable to greenhouse gases produced by human activities. Climate change is an ongoing process in the Southwest with associated effects to Chiricahua leopard frogs. Mean annual temperatures rose 2.0-3.10F in the American Southwest in the 20th century, and are predicted to rise 8.1-11.0 0F in the 21st century (Southwest Regional Assessment Group 2000).

Predictions of changes in precipitation are less certain; however, some models predict as much as a doubling of annual precipitation, with the largest increases in winter precipitation (Southwest Regional Assessment Group 2000). But these predictions contrast with current trends of a warming North Atlantic and cooling tropical Pacific, with associated changes from a relatively wet period to drought, insect outbreaks in southwestern forests, and increasing wildfires (Patterson 1997, Betancourt 2004). Some models predict dramatic changes in southwestern vegetation communities as a result of climate change (Thompson et al. 1997). Arizona's forested areas could decline by 15-30 percent as a result of hotter and drier conditions that fuel wildfires, as well as warmer winters that promote forest insect outbreaks. Arizona's two largest wildfires on record occurred in 2002 and 2005 (Arizona Climate Change Advisory Group 2006).

Climate change can occur abruptly, with associated major changes in the environment (National Academy of Science, Committee on Abrupt Climate Change 2002). The potential for climate change and the uncertainty as to how it may manifest, particularly in regard to precipitation patterns, add considerable uncertainty to predicting the future status and threats to the Chiricahua leopard frog, as well as the strategies needed to recover the species. For instance, drought driven by climate change could result in extirpations of Chiricahua leopard frogs from stock tanks and other marginal habitats subject to drying. If rainfall increases, potential habitat for Chiricahua leopard frogs may increase, as well. Yet, increased precipitation may provide more opportunities for predators to spread and adversely affect remaining frog populations, offsetting any benefits due to more mesic conditions for Chiricahua leopard frogs.

Drought would likely reduce habitat for and invasion by non-native predators. Increasing temperatures have the potential to alter frog breeding phenology, with unknown effects to frog populations and predators of Chiricahua leopard frogs (Blaustein et al. 2001, Beebee 2002). During drought, proximity of suitable drought-resistant habitats may be critical to persistence of each frog population. If Chiricahua leopard frogs cannot disperse from drying habitats and reach suitable habitat, droughts are likely to produce major, though not necessarily irreversible, population declines. Small drought refugia, such as crevices in concrete near an overflowing drinker, or an accessible water storage tank or drinker that the frogs can get into and out of can become critically important for survival of frogs.

Potential direct effects of increased temperatures on the species include earlier reproduction in spring, more rapid development, shorter period of hibernation, longer period of aestivation, changes in abilities to find food, spread of infectious disease, and changes in immune function (Blaustein et al. 2001, Beebee 2002). Increasing temperatures may affect the population dynamics of chytridiomycosis, because the fungi's growth (Collins et al. 2003, Piotrowski et al. 2004) and effectiveness of antimicrobial peptides on the skin of ranid frogs (Longcore et al. 1999) are temperature dependent. If increased temperatures are coupled with reduced precipitation, a variety of indirect effects could occur as well, including habitat loss and fragmentation, and changes in interactions with prey, competitors, predators and parasites, which may form the most serious adverse consequences of climate warming on amphibian populations.

Atmospheric ozone depletion over the last 40 years has resulted in increased ultra-violet (UV)-B radiation reaching the earth's surface. Potential direct effects of increased solar UV radiation on amphibians consist of abnormal embryonic and larval development, damage to the eye and skin, and systematic effects through the suppression of the immune system. Indirect effects include changes in the relative abundance and species composition of competitors, predators and/or parasites, as well as toxic effects of chemicals produced or released as a result of photochemical reactions. Nocturnal and secretive habits of many amphibians protect them from exposure to solar UV. Pigmentation and an ability to repair UV-induced damage are likely to determine the sensitivity of those species that are regularly exposed to solar radiation at different phases of their life cycle (Ovaska 1997). (42-43)

Chum salmon (Hood Canal summer run DPS) *Oncorhynchus keta* pop. 2
Hood Canal & Eastern Strait of Juan de Fuca Summer Chum Salmon Recovery Plan 2007

The reduction of stream and estuarine productivity and capacity, caused by habitat degradation, is cumulative with the negative effects of climate and excessive fishery exploitation. (49)

Three primary factors have combined to cause the decline of summer chum salmon in both Hood Canal and Strait of Juan de Fuca streams (WDFW and PNPTT 2000). They are: 1) climate related changes in stream flow patterns; 2) fishery exploitation, and 3) habitat loss. (71)

6. 3. 1. Climate Change and Fishery Exploitation The long-term loss of habitat productivity and capacity will impact summer chum salmon by lowering survival rates (population resiliency) and reducing potential population size. When Hood Canal/Eastern Strait of Juan de Fuca summer chum salmon began to experience the added pressures from climate change and new fishery exploitation, the populations collapsed. In 1979, summer chum run sizes and subsequent escapements were very low because of the effects of unfavorable stream flows on the 1975 and 1976 brood production (WDFW and PNPTT 2000). This poor performance was evident in chum salmon stocks statewide. The summer chum populations of Hood Canal (with the exception of Union River) were the only chum stocks that did not immediately recover from the low return levels of 1979 (WDFW and PNPTT 2000). WDFW and PNPTT (2000) discusses the potential impacts from climate change and particularly, the possible impacts to stream flows during spawning and incubation (see SCSCI section 2. 2. 2. 4). The co-managers further conclude, however, that (A)ny analysis of climate change in relation to stream flow and the decline of summer chum salmon populations cannot be isolated from human-caused habitat alterations. (72)

Climate shifts like those observed in the past 30 years, with their associated stream flow changes, likely have posed little threat to summer chum populations before the cumulative effects of habitat changes from human development became manifest. (72)

Evidence suggests decreasing trends in certain summer chum watersheds, a fact that may be exacerbated by climate change. (294)

...manage for the primary importance of maintaining metapopulation structure. In other words, while each local leopard frog population is important, it is the metapopulation that is essential. The occasional loss of individual leopard frog populations as a result of biological, climatic, economic, or other factors may therefore be acceptable, so long as the affected metapopulation persists. (A-3)

2) Restore hydrological regime through watershed management, retirement of stream diversions, and local restrictions on groundwater pumping on public lands...Water flows will vary with climatic cycles and thus may not be consistently maintained, particularly in drought conditions. Therefore, measures should be proposed and agreements implemented to secure the needed flows when diversions, impoundments, or urban wastewater flows threaten the integrity of the hydrological regime. (H-15)

Desert tortoise (Mojave DPS) *Gopherus agassizii* pop. 1
Draft revised recovery plan for the Mojave population of the desert tortoise (Gopherus agassizii) 2007

E. Other Natural or Manmade Factors Affecting its Continued Existence

Global climate change and drought are potentially important long-term considerations with respect to recovery of the desert tortoise. The Earth's climate has warmed by nearly 1.5 degrees Fahrenheit over the past 100 years (Walther et al. 2002), and anthropogenic emissions of greenhouse gases play a major role in this process (Weltzin et al. 2003). There is now sufficient evidence that recent climatic changes have affected a broad range of organisms with diverse geographical distributions (Walther et al. 2002). While little is known regarding direct effect of climate change on the desert tortoise or its habitat, predictions can be made about how global and regional precipitation regimes may be altered and the consequences of these changes (Weal. 2003; Seager et al. 2007). Such predictions need to be developed specifically for the desert tortoise to help inform recovery efforts. (16)

E. Other Natural or Manmade Factors Affecting its Continued Existence
Climate Change. The Earth's climate has warmed by nearl 1.5 degrees Fahrenheit over the past 100 years (Walther et al. 2002), and anthropogenic emissions of greenhouse gases play a major role in this process (Weltzin et al. 2003). While this warming is not uniform with regard to time and space, the rate of warming during the last 30 years has generally been greater than at any other time during the the last 1,000 years. In many regions there is an asymmetry in warming, as well as precipitation, which is likely to contribute to variation in ecological dynamics across ecosystems. There is now sufficient evidence that recent climate changes have affected a broad range of organisms with diverse geographical distributions (Walther et al. 2002). Interactions between altered precipitation patterns and other aspects of global change are likely to affect natural and managed terrestial ecosystems. For example, climate models predict that Joshua trees will no longer be able to persist within Joshua Tree National Park through the 21st century (Cole et al. 2005). While little is known regarding direct effects of climate change on the desert and habitat, predictions can be made about how global and regional precipitation regimes may be altered and the consequences of these changes (Weltzin et al. 2003; Seager et al. 2007).

Climatic regimes are believed to influence species' distributions through species-specific physiological thresholds of temperature and precipitation tolerance. Warming temperatures and altered precipitation patterns may result in distributions shifting toward the poles and/or to highens, depending on resource availability (Walther et al. 2002). We may expect this response in the desert tortoise, thereby reducing the viability of lands currently identified as refuges or critical habitat for the species. Seager et al. (2007) ran a series of climate models simulations on the precipitation history and future of the southwestern United States and northern Mexico that consistently showed a severe drying trend in this region throughout the 21st century, especially in areas where evapotranspiration exceeds precipitation.

Experiments in Nevada at the Free-Air Carbon Dioxide (CO2) Enrichment Facility to predict the possible complex ecological and biogeochemical changes in semi-desert ecosystems by increasing atmospheric CO2 have been ongoing since 1997 (Hamerlynck et al. 2000; Smith et al. 2000; Huxman and Smith 2001). Because deserts are both water- and nutrient- systems and native plants are so slow growing, it is still too early to say with any confidence how even the most intensively studied desert shrub communities of the southwestern States will respond to rising CO2 (Lioubimtseva and Adams 2004). However, results from the Free-Air CO2 Enrichment Facility site demonstrate that cheatgrass responds to increasessuch that it is far more productive than native plants during wet years (Smith et al. 2000). As discussed in the Fire section, non-native annual grass invasions are known to increase thecy and intensity of fires, which has a dramatic negative effect on desert water cycles and habitat (Hamerlynck et al. 2000).

Direct climatic effects on growth and development, spatial distribution, and species interactions are apparent in amphibians and reptiles, which, in common with other ectotherms, are heavily influenced by environmental conditions. Both seasonal temperature and humidity affect their reproductive physiology and population dynamics (Walther et al. 2002). It remains unclear how regional changes in climate may affect the desert tortoise; however, some observations relative to drought have been documented in the past. (99-100)

5.2.4 Determine the importance of corridors and physical barriers to desert tortoise distribution and gene flow...Determining the importance of corridors and barriers will allow population models to be made spatially explicit relative to current land management (e.g., population and habitat fragmentation due to roads and urbanization) and potential distributional shifts resulting from climate change. (57)

5.2.3 Model desert tortoise demography relative to habitat condition to determine the proportion of habitat that needs to be occupied (or is available to be occupied) for recovery….As habitat-specific demography is clarified (5.3.2), population models should be developed to refine estimates of habitat quantity and tortoise occupancy necessary to sustain populations into the future. Models should incorporate predicted effects of climate change on desert tortoise demography, as well as on the current composition of tortoise habitat. Information from this recovery action is essential to refining Recovery Criterion 3a relative to the amount of habitat needed to conditions for delisting. (57)

Indiana bat *Myotis sodalis*
Indiana Bat (Myotis sodalis) Draft Recovery Plan, First Revision 2007
http://ecos.fws.gov/docs/recovery_plans/2007/070416.pdf

Few specific drivers of this apparent population shift have been rigorously explored or identified, but inappropriate hibernacula temperatures (see Tuttle and Kennedy 2002) and regional climate change are either known or generally suspected in having had a role. We currently have an incomplete understanding of the links between M. sodalis' hibernation energetics, its biogeographical distribution, and climate change. However, the predictive modeling approach recently used by Humphries et al. (2002) for M. lucifugus could provide some insight into M. sodalis' potential winter distribution if global climate change occurs. (22)

Apparent Regional Population Trends and Climate Change
It is nearly impossible to consider the geographic positions of states where Indiana bat populations are declining and states where they are stable or increasing without considering the possibility that regional and/or global climate change is driving some changes in Indiana bat populations. Table 3 reveals a clear division in apparent population trends between states in the northern portion of the Indiana bat's range versus states in the southern portion of the range (Clawson 2002). Steep declines in Kentucky and Missouri hibernacula have largely contributed to the apparent decline in the southern population during the 45-year period from 1960 through the present. In contrast, there apparently has been an overall increase in population in northern states over the same time period. The role of climate change and its effect on temperatures in hibernacula need investigation. Although current data are not sufficient to definitively determine the cause of apparent regional disparities, it appears that both protection of hibernacula and suitable temperature regimes may be key to understanding trends in the overall population and recovery of the species. (37)

Climate Change. Potential impacts of climate change on temperatures within Indiana bat hibernacula were reviewed by V. Meretsky (pers. comm. , 2006). Climate change may be implicated in the disparity of population trends in southern versus northern hibernating populations of Indiana bats (Clawson 2002), but Meretsky noted that confounding factors are clearly involved. Humphries et al. (2002) used climate change models to predict a northern expansion of the hibernation range of the little brown bat; such modeling would likely result in predictions of range shifts for Indiana bats as well. Potential impacts of climate change on hibernacula can be compounded by mismatched phenology in food chains (e. g. , changes in insect availability relative to peak energy demands of bats) (V. Meretsky, pers. comm. , 2006). Changes in maternity roost temperatures may also result from climate change, and such changes may have negative or positive effects on development of Indiana bats, depending on the location of the maternity colony. The effect of climate change on Indiana bat populations is a topic deserving additional consideration. (100-101)

Climate change and wind turbines may present additional threats to the species; the full impact of these factors will be realized with time. (113)

Research is necessary in numerous key areas including but not limited to...effect of global warming on the species' distribution and hibernacula. (114)

Peripheral populations can play an important role in conservation. Their relative isolation and lower abundance typically results in less genetic diversity than core populations due to genetic drift caused by reduced gene flow and founder effects (Lesica and Allendorf 1995, Vucetich and Waite 2003). However, concomitant processes in peripheral populations may also produce distinctive genetic characteristics…. As previously discussed, peripheral populations may occupy atypical or less favorable habitats (Lomolino and Channell 1995, Channel and Lomolino 2000a, 2000b). To persist, these individuals must adapt to different and possibly more extreme environmental factors and selective forces. Additionally, peripheral populations may be genetically and ecologically different from other peripheral populations and the core populations (Lomolino and Channell 1995). Further, peripheral populations may be better adapted to long-term rangewide environmental changes, such as global climate change (Hunter 1991, Araujo and Williams 2001). These individuals may be best adapted to establishing themselves in the shifting habitats created by changing climate (Fraser 2000). (115-116)

3.2.3 Model the potential impact of climate change, alterations to physical structure, and surrounding habitat modifications on projected use of hibernacula by Indiana bats.

Alterations to cave and mine entrances have been generally recognized to change temperature and other conditions within hibernacula, as gross modifications to surrounding habitat (e. g. , deforestation, construction of buildings). Recent scientific studies have also called attention to the likelihood that global climate change is influencing the distribution of bats, including the geographic distribution of hibernacula. An improved understanding of Indiana bat physiological requirements for hibernation and characteristics of hibernacula will be achieved under objectives 3. 2. 1 and 3. 2. 2. Based on these studies, modeling efforts should be conducted that consider the influence of structural alterations, surrounding habitat modifications, and climate change on the future suitability of hibernacula used by Indiana bats throughout the species current and projected future distribution. (162-163)

Northern spotted owl *Strix occidentalis caurina*
Draft Recovery Plan for the Northern Spotted Owl (Strix occidentalis caurina) 2007
http://ecos.fws.gov/docs/recovery_plans/2006/060118.pdf

The panel identified disease and the effect of climate change on vegetation as potential and more uncertain future threats. (18, 25)

Spalding's catchfly *Silene spaldingii*
Recovery Plan for Silene spaldingii (Spalding's Catchfly) 2007
http://ecos.fws.gov/docs/recovery_plan/071012.pdfhttp://ecos.fws.gov/docs/recovery_plan/071012.pdf

S. spaldingii is affected by a variety of factors including...annual climatic conditions (i.e., drought cycles); climate change… (1)

Causes aside, global temperatures are increasing (USEPA, in litt. 2000, p. 1). The effects of this climate change are speculative, but it has the potential to affect rare plants such as Silene spaldingii. Researchers speculate that this warming will alter rainfall patterns, with some regions becoming drier and others wetter (Given 1994, pp. 33-34). Within the Pacific Northwest a recent model predicts warmer and wetter winters in 80 years (U.S. Department of Energy 2004, p. 1). Plants are stationary, moving through dispersal, colonization, and recruitment events. Because plants are stationary and move slowly through the aforementioned events, it is thought they can't move quick enough to keep up with a shifting climate, and are more susceptible to global warming than are wildlife species (Wilson 1989, p. 114). Furthermore, fragmentation and isolation limits movement opportunities. (46)

Impacts from Drought and Global Warming: 1. conserve and expand populations in each physiographic region; 2.1 general management plans; 2.3 habitat management plans; 2.4 monitor; 2.10 funding. (C-3)

Impacts from Drought and Global Warming: 1. conserve and expand populations in each physiographic region; 2.1 general management plans; 2.3 habitat management plans; 2.4 monitor; 2.10 funding (C-3)

Impacts from Drought and Global Warming: 2, 3, 4 (C-3)

2.3. Habitat management plans and recovery actions should manage for impacts and threats to Silene spaldingii populations and habitat both at key conservation areas as well as at smaller populations. Threats include...impacts from prolonged drought and climate change; and an inadequacy of existing regulatory mechanisms. All of these threats should be addressed both through habitat management plans and recovery actions both at key conservation areas as well as at smaller populations. (92)

Steelhead trout (Upper Columbia River DPS) *Oncorhynchus mykiss* pop. 12
Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan 2007
http://www.nmfs.noaa.gov/pr/pdfs/recovery/proposed_uppercolumbiasalmon.pdf

The potential impacts of global climate change are recognized at national and international levels (Scott and Counts 1990; Beamish 1995; McGinn 2002). Many climate models project changes in regional snowpack and stream flows with global climate change. The effects of these changes could have significant effects on the success of recovery actions and the status of listed fish populations in the Upper Columbia Basin. The risks of global climate change are potentially great for Upper Columbia stocks because of the sensitivity of salmon stocks to climate-related shifts in the position of the sub-arctic boundary, the strength of the California Current, the intensity of coastal upwelling, and the frequency and intensity of El Nino events (NPCC 2004). Bull trout are particularly sensitive to water temperatures and it is uncertain how global climate change will affect their habitat. More research is needed to address the effects of climate change on ocean circulation patterns, freshwater habitat, and salmon and trout productivity. (105)

Whooping crane *Grus americana*
International Recovery Plan for the Whooping Crane (Grus americana), Third Revision 2007
http://ecos.fws.gov/docs/recovery_plans/2005/050111.pdf

Global warming and associated climate changes constitute a potential threat to whooping crane recovery. Based on climate records and calculated rates of rises in greenhouse gas concentration from human activities, models of global climate change suggest that average global surface temperatures will increase by 1.4 and 5.8ºC (2.5 and 10.4ºF) by the end of this century (National Academy of Sciences 2005 website: http://www4.nas.edu/onpi/webextra.nsf/web/climate?OpenDocument). In the Northern Hemisphere, from 1951 to 1990, average minimum winter temperature rose 2.9ºC, while average summer maximum temperature rose 1.3ºC (Crozier 2003). In addition to rising temperatures, other climate factors such as the rising of sea level, flooding of coastal wetlands, drying of interior wetlands, and intensifying of precipitation events may impact the whooping crane. Although the frequency of future hurricanes is uncertain, hurricanes are expected to become stronger and bring more intense rainfall than hurricanes at present, due to increases in sea surface temperatures (NOAA website: http://www.gfdl.noaa.gov/~tk/glob_warm_hurr.html, updated March 23, 2006). Coastal wetlands are particularly vulnerable to erosion, changes in salinity and microclimate conditions, changes in groundwater tables, and habitat loss from expected rises in sea level and hurricane damage (EPA Global Warming Impacts Coastal Zones website: http://yosemite.epa.gov/OAR/globalwarming.nsf/content/ImpactsCoastalZones.html).

Climate change is expected to alter the physiology, distribution, phenology, and adaptation of organisms (Hughes 2000, Menzel et al. 2001, Stenseth et al. 2002, Peterson 2003, Parmesan and Yohe 2003). In turn, these processes may affect growth rates, individual size, individual mobility, overall fitness, reproductive success, and population demographics (Stenseth et al. 2002). Changes in ecosystem functioning, such as cycling of nutrients, and interactions among whooping cranes and their biotic resources, such as food species, plant communities, predators, parasites, competitors, and mutualists, are difficult to predict and involve an understanding of an ecosystem's resistance and resiliency to interference (Chapin et al. 2000). Habitat specialization of birds has been associated with sharper declines in population abundance (Julliard et al. 2003, Peterson 2003, Thomas C. et al. 2004, Thomas J. et al. 2004). Warming temperatures have caused a northward shift in bird species' ranges, hastened the timing of winter and summer activities, and are predicted to decrease biodiversity world-wide (Thomas and Lennon 1999, McCarty 2001, Thomas C. et al. 2004). For the whooping crane, this could affect current wintering areas, summering locations, and the timing of breeding and migration. These changes may alter the extent to which a bird's life cycle is synchronized with its food supply and nest site availability.

If climate change results in drier conditions either on the summer or wintering grounds, whooping cranes would face great difficulties from disruptions to the ecology of those areas. Any changes that adversely affect the water regime of WBNP could have severe impacts on whooping crane reproduction. Permanently lowered water tables, for example, would shrink wetlands, reduce the availability of quality nesting sites, reduce invertebrate food availability, and allow predators to access nests and young. Chick survival is reduced during dry years in WBNP (Kuyt et al. 1992). On the winter area, a reduction in rainfall would reduce inflows and reduce the blue crab population that the cranes rely on for food. Global warming and associated sea level rise, combined with land subsidence, is projected to be about 17 inches on the Texas coast over the next 100 years (Twilley et al. 2001). This would reduce suitability of salt marsh and open water areas, making much of the present acreage too deep for use by whooping cranes (Tom Stehn, ANWR, pers. comm.). (25-26)

The majority of breeding habitat is located in WBNP...the potential critical habitat is protected from a number of anthropogenic threats. It may be threatened however, by climate change that could result in more severe weather events including drought. (31-32)

1.5.3.1. Maintain WBNP. Whooping Crane Recovery Plan 2006 Effective management and research is needed on the wintering grounds to maintain the quality of crane habitat at WBNP. Long-term studies are needed to detect and address any detrimental changes from climate change or other causes. (49)

1.5.3.9. Monitor global warming. The potential for sea level rise and climate change related to global warming should be monitored to address possible impacts to whooping crane habitat. Research and appropriate management response will be needed to protect coastal ecosystems and nesting habitat. (50)

1.5.2.6. Monitor global warming The expected sea level rise along with climate change caused by global warming will have a major negative impact on whooping crane wintering habitat. Continued research and management will be needed to protect this habitat. (51)

Akiapolaau (honeycreeper) *Hemignathus munroi*
Revised Hawaiian Forest Birds Recovery Plan 2006
http://ecos.fws.gov/docs/recovery_plans/2006/060922a.pdf

Climate change could enable the transmission of pox and malaria at higher elevations, further threatening remaining populations of endangered birds (Benning et al. 2002). (1-5)

2.5.1.4 Work to stop global climate change. (Priority 1) Global warming and local climate change are a serious threat to listed species in Hawai`i primarily because of the potential for movement of disease carrying mosquitoes into higher elevation avian refugia currently free of mosquito breeding sites. This work will require cooperation by appropriate agencies and entities to develop agreements and technologies needed to slow greenhouse gas emissions, asignificant factor contributing to global climate change. (4-66)

Akohekohe (crested honeycreeper) *Palmeria dolei*
Revised Hawaiian Forest Birds Recovery Plan 2006
http://ecos.fws.gov/docs/recovery_plans/2006/060922a.pdf

Climate change could enable the transmission of pox and malaria at higher elevations, further threatening remaining populations of endangered birds (Benning et al. 2002). (1-5)

2. 5. 1. 4. Work to stop global climate change. (Priority 1) Global warming and local climate change are a serious threat to listed species in Hawai`i primarily because of the potential for movement of disease carrying mosquitoes into higher elevation avian refugia currently free of mosquito breeding sites. This work will require cooperation by appropriate agencies and entities to develop agreements and technologies needed to slow greenhouse gas emissions, asignificant factor contributing to global climate change. (4-66)

Fin whale *Balaenoptera physalus*
Draft Recovery Plan for the Fin Whale (Balaenoptera physalus) 2006
http://www.nmfs.noaa.gov/pr/pdfs/recovery/draft_finwhale.pdf

G.14 Climate and Ecosystem Change Climate change has received considerable attention in recent years, with growing concerns about global warming and the recognition of natural climatic oscillations on varying time scales, such as long term shifts like the Pacific Decadel oscillation or short term shifts, like El Niño or La Niña. Evidence suggests that the productivity in the North Pacific (Quinn and Neibauer 1995; Mackas et al. 1989) and other oceans, is affected by changes in the environment. Increases in global temperatures are expected to have profound impacts on arctic and sub-arctic ecosystems and these impacts are projected to accelerate during this century. The potential impacts of climate and oceanographic change on fin whales will like impact habitat availability and food availability. Site selection for whale migration, feeding, and breeding for fin whales may be influenced by factors such as ocean currents and water temperature. Any changes in these factors could render currently used habitats areas unsuitable. Changes to climate and oceanographic processes may also lead to decreased productivity in different patters of prey distribution and availability. Such changes could affect fin whales that are dependent on those prey. (I-32)

Hawaii 'Akepa *Loxops coccineus coccineus*
Revised Hawaiian Forest Birds Recovery Plan 2006
http://ecos.fws.gov/docs/recovery_plans/2006/060922a.pdf

Climate change could enable the transmission of pox and malaria at higher elevations, further threatening remaining populations of endangered birds (Benning et al. 2002). (1-5)

2. 5. 1. 4 Work to stop global climate change. (Priority 1) Global warming and local climate change are a serious threat to listed species in Hawai`i primarily because of the potential for movement of disease carrying mosquitoes into higher elevation avian refugia currently free of mosquito breeding sites. This work will require cooperation by appropriate agencies and entities to develop agreements and technologies needed to slow greenhouse gas emissions, asignificant factor contributing to global climate change. (4-66)

Hawaii creeper *Oreomystis mana*
Revised Hawaiian Forest Birds Recovery Plan 2006
http://ecos.fws.gov/docs/recovery_plans/2006/060922a.pdf

Climate change could enable the transmission of pox and malaria at higher elevations, further threatening remaining populations of endangered birds (Benning et al. 2002). (1-5)

(4-66)

Hawaiian monk seal *Monachus schauinslandi*
Recovery Plan for the Hawaiian Monk Seal (Monachus schauinslandi), Revised 2006
http://www. nmfs. noaa. gov/pr/pdfs/recovery/draft_hawaiianmonkseal.pdf

The loss of terrestrial habitat is a significant issue of concern in the NWHI, especially habitat loss due to environmental factors such as storms and sea level rise that could further exacerbate this problem in the future. While some habitat loss (e. g. , the subsidence of Whaleskate Island at FFS) has already been observed, sea level rise over the longer term may threaten a large portion of the resting and pupping habitat in the NWHI (Baker et al. , 2006). (34)

Changes in climate and oceanographic conditions may affect pinnipeds by changing availability of their prey.... (37)

There has been no known alteration of habitat to preclude attainment of this presumed post-WWII population level (though there are outstanding questions about effects of fisheries and about normal or global climate change effects on the productivity of the NWHI ecosystem). (132)
