# ECONOMIC STATUS OF THE AGED IN URBAN HOUSEHOLDS 

Barkey S. Sanders*

Tue economic phiert of the agred has beon a sourco of public concern in rocont years. Becnuso of this public interest it is instructive to explore the comparative economic status of households with aged persons and of other households. Such an exploration does not afford a preciso knowledgo of the status of the agod, since in some instances the income of the houselold in which aged persons live may not be an exact roflection of the income of the aged persons. ${ }^{1}$ Novertheless, a comparison of the economie status of households in which there are one or more persons aged 65 or over and that of other housoholds is significunt oconomically and sociologically. The results, if not conclusivo, are at least suggostivo of the comparative economic insecurity of aged persons and other groups in the population.
The focusing of publie attention on the needs of the aged is likely to give rise to the danger of maderemphasis on other segments of the population unless the comparative economie status of these other groups also reeceives consideration. In prior analyses of data from the study of family composition in the United States, it has become apparent repentedly that chiddren-rather than the aged -are most frequently found in families with lowest incomes, and that children-and not the uged constitute the age group which is least favored ceonomically. ${ }^{2}$ Although large numbers of aged persons may be without means, as a group, the aged may not be my more insecure, and may even have grater secmity, than some other groups in our population whose needs have not received as much publie attention.
Data from the study of family composition in the United States provide a basis for comparing the relative ceonomie security of various elements of the urban population. The distribution by

[^0]income of houscholds ${ }^{3}$ in which the head of the houschold is aged 65 and over and those in which he is under 65 is shown in percentage form in tablo 1 and in chart I.

For all houscholds withont respect to size, the proportion of households on relief ${ }^{4}$ is approximately the same whether the head of the housohold is 65 or over, or whether he is younger. Households headed by aged persons have a relatively higher percentage in the income group of less than $\$ 1,000$ and the income group of $\$ 3,000$ and over. The relatively greater concentration of the aged in the lowest income group does not reflect the true economic position of households with aged heads, because of the smaller average size of houscholds with aged heads, as indicated in table 1.

In households with one, two, and three mombers there is a somewhat greater concentration of those with aged hends than others in the income categories of relief and under $\$ 1,000$, and lower proportions in households with incomes of $\$ 1,000-$ 2,999 ; in the income groups of $\$ 3,000$ and over, the proportion of houscholds with aged heads is relatively large. In households with four or more members, fewer houscholds with aged heads are found in the group on relief and generally more mong those reporting incomes of $\$ 2,000$ or more; the differences in the proportions are greater with increasing household size. If household size is considered in relation to income, it is apparent that in the smaller households-one to three members-those headed by aged persons have an coonomic status more favorable than that of houscholds of four or more with heads under the age of 65 . About 78 percent of the housoholds with heads aged 65 or over are small households of one, two, or three persons, where the income is shared by fewer persons. The corre-

[^1]sponding proportion of houscholds with heads aged $16-59$ is only 56 percent.

It may be assumed with some measure of accuracy that in the larger households members other than the aged head are more likely to be the income-producers; however, previous amalysis has led to the belief that it is in economically secure households that adult children continue to live with the parents, at least until marriage. Nor does the somewhat less favorable status of households with aged heads, as observed in those with one, two, and three members, prove unequivocally the less favorable status of such houscholds, except, in those consisting of one person only, which account for 20 percent of the households with aged heads. Even in this group the real differences may be less marked than the statistics would indicate. The higher proportion on relief may not be an
accurate yardstick of relative cconomic need, since the public attitude is much more favorable toward granting aid to the aged than to young men or to men of intermediate ages, even though objectively they may be equally in need.
In houscholds with two and three members, especially in two-person houscholds in which the head is less than 60, we are dealing in large part with households without children- a group which has a more favorable economic status. Tho higher proportion of smaller houscholds with aged heads in the highest income category, the deeidedly more favorable income distribution of households with aged heads in those with four or more members, the publie attitude in granting relief, and the relation between income and the absence of children in houscholds with younger heads would minimize the inference that households with aged hoads are

Chart I.-Percentage distribution of urban households by income staths, for households of sprcified size wilh specified age of head

economically less secure than those with younger heads.

In assessing the relative economic position of households with aged heads as compared with other households, an element to be considered is the fact that the incomes reported in table 1 are limited to cash income, excluding such economic assets as homo ownership, savings, and investments, in which the houscholds with aged heads would make a more favorable showing than those with younger heads. Moroover, estate-tax returns in the
 Bulletin No. 642, Aprll 1038, i. 86.)

United States for 1023-25, the latost years for which an age distribution is available, show that the proportion of taxed estates of decedents aged 25 to 59 years was only 40 percent of that for decedents aged 60 and over. ${ }^{\circ}$ When the oloment of property ownership and savings is considored, it would be difficult to deduce, from the rolationships shown in table 1 and chart $I$, that households with aged heads are, in general, cconomically loss favored than those with younger heads.

Tho discussion up to this point has been in terms of the hend of the houschold and has shown that the income distribution for households in which the head is 65 years or older is more favorable than that for households headed by porsons under age 65. Shifting the amalysis to consider members rather than heads of households broadens the seope of the comparison to take in all agod

- See U. S. Burenu of Intermal Revenue, Statisice of Income, 1022, In. 70-72; 1923, 1p. 48-60; and 1024, pp. 80-01.

Table 1.-Number of urban houscholds by size of household and age of head of household, and percentage distribution by income stctus

[^2]persons in the houscholds studied. In terms of the income distribution of housoholds according to the ages of the members (tablo 2), the same relative relationships hold between income and age as were found when the analysis was in terms of age of the head of the household.

Children have the greatest concentration in the low-income groups in households of each size. When persons aged 65 and over are compared with those in ages 16-59, a higher proportion of the aged in households with one, two, or three members is found in the income categories of relief or less than $\$ 1,000$, and fewer of them are in the income categories of $\$ 1,000$ - $\$ 1,999$ but not in the group $\$ 3,000$ and over. In larger households-those with four or more members - the relative proportion of aged in houscholds on redief, and very often in those with incomes of less than $\$ 1,000$, is smaller. ('onversely, the proportion of aged in houscholds with high incomes is greater. Approximately two-thirds of the aged are in households with one to three members, while less than 45 pereent of persons in ages $16-59$ are in these small houscholds (table 3).

With incrensed household size the relative

economic status of households with adults aged 16-59 becomes less favorable than that of housoholds with aged members; more than half the adults in ages 16-59 aro in households with four or more members, with an coonomic status distinctly less favorable than that of households of aged persons, regardless of housohold sizo. This rolntive disadvantage is omphasized whon por capita income of these housoholds is considered.

I Inclutes houtsoholids with 11 or more persons.

- Porsons in rullef hobsoholds were assignod per capita incomes of less than $\$ 250$ a year.

The per capita incomes given below for persons in specified age groups were obtained by dividing the housohold income ${ }^{7}$ by the number of members in the housohold sharing the income and by averaging together the income of persons in specified ages from difforont housoholds with varying per capita incomes. The ostimatos of per capita income thus obtained are as follows:

| All ages | \$439 |
| :---: | :---: |
| Under 16 years. | 301 |
| 16-24 years. | 371 |
| 25-44 years. | 486 |
| 45-59 years. | 561 |
| 60-64 years. | 608 |
| 65 years and over | 577 |

For the succossive age groups there is a rise in average per capita income to a maximum for tho age group 60-64. The per capita income for persons aged 65 and over is almost twice that for persons under 16 years and is higher than the per capita incomes of groups in the ages 16-59.

From this comparison it appears that households with aged members have a higher average per capita income than those with younger per-

[^3]Chart II.-Percentage distribution of persons in urban households by age artl per capita income groups

sons, especially persons under 16 yours of age. Since average per capita expenditures for various items in the houschold budget may be lower in large households, because of such obvious aconomies as can be achieved in sholter, fucl, and light, the average per capita income of $\$ 577$ for persons in ages 65 and over may not be much more favorable than the average of $\$ 48 t$ for persons in ages

1 Persons in relief households were assigned fer capita incomes of less than \$2ran a yenr.

25-44, who are more often members of larger families. Another offsotting factor is the fact that persons in ages 16-59 are more ofton in houscholds with childron, for whom per capita expenditures may be lower.

In terms of dollar amomets, however, households with aged members have more than their proportionate share of income, even when allowance is made for the relatively higher concentration of aged persons in the higher income eategories. This fact is demonstrated in table 4, which shows the proportion of persons of specified ages living in households with per eapita ineomes of at least $\$ 250, \$ 350$, or $\$ 500$. In all households, irrespective of size, the income distribution of aged persons is more favorable than that of persons in ages below (00), and especially of persons under the uge of 16 . For instance, more than ( 64 percent of persons aged 65 and over are in households with per capita incomes of $\$ 250$ or more; the corresponding percontage for children under 16 is 40 and for those in ages $16-59$ it is 60 (ehart 11). No offsetting allowance is mado here for the fact that a larger proportion of persons in younger ages are in larger households, with resulting economies in the cost of living.

When variations in per capita income are related to household size, the relationships in tables 1 and 2 are confirmed. In one and two-person households, and to a slight extent in those with three members, the proportion of persons aged 6.5 and over, for each per capita income group, is less than the proportion of persons in ages $16-59$. In houscholds of four or more persons, the proportions of aged are higher than the proportions for persons in ages 16-59. In each size of household, children have the lowest average incomes, and the relative disparity in favor of aged persons becomes grenter for larger households. For instance, in threeperson households 66 pereent of the ehiddren and 68 pereent of the aged are in households with minimum per capita incomes of $\$ 250$. The corresponding pereentages for households of seven persons are 17 and 37 percent. The per capita income of the aged in houscholds of one, two, and three, though less favorable than that of persons uged 1659 in houscholds of these sizos, is much more favorable than that of persons aged 16-59 in households with four or more members.

Despito their limitations, these analyses of households in teme of per capita income of dif-

Chart 111.-Percent of persons with specified per capita income in urban households of specified sise, for persons aged 65 and over and for all persons in broken households headed by a widowed, divorced, or separated woman

ferent ago groups do not support the viow that aged persons as a group are conomically the least secure in our population. If anything, available data would suggest that tho aged havo perhaps a larger relativo proportion who are conomically most favored than do persons in other age groups.

As a group, the aged may spend as much from their own resourecs for the support of younger persons as is spent, in the aggregate, by younger persons toward the support of the aged. The plausibility of this inference may be tested by an analysis of the employment status of aged persons and others in households with one or more members aged 65 and over and by an examination of home ownership for households with aged members as compared with other households. Such an malysis will be presented in a subsequent paper.

From the tabulations examined thus far, it appears that on the average the income available

from wages or from other cash-income producing sources, in households which include persons who are 65 years or over, is probably as high as or higher than that for households with other alults. The proportion of aged among the needy and nomong those who have little or no resourees of their own may be, in general, somewhat higher than among other adults, in the light of ceonomies related to family size, the lesser cost of living for children, and the probability that more often than for other age groups the income of the household may not reflect the economie status of che aged person. ${ }^{8}$ Nevertheless, it camot be said that the aged as a group are as needy as certain other segments in the population such as children; broken families, especially those with a widowed mother; families with disabled heads; and, in

[^4]general, families which are deprived of the earnings of the principal wage amener through death, disability, or chronic unemployment. The less favorable eronomic status of these groups is illustrated in tables 5, 6 , and 7 .

Variations in per capita income in relation to household size are presented in table 5 for households headed by a woman who is widowed, divorced, or separated from her hushand. Comparison with the corresponding data for all households (table 4) indientes that, except in households of one person, these broken households are less favored economically than are houscholds with aged members. These rehtionships are shown graphically in chart III.

Table 6 provides a comparison of the relative income status of households headed by disabled persons under (65 yours of age and houscholds with one or more members aged 65 and over. The

Table 7.-Number of persons aged 65 and orer in urban single-family households and numbor of such households wilh no gainful worker, with unemployed head, and wilh momployed sainful worker, ard percontake distribution by income status

comparison has been limited to households consisting of only one family, since data for households consisting of more than one family are not available at this timc. ${ }^{\circ}$ A striking contrast is found, in all household sizes, in favor of households of aged persons as compared with those headed by disabled persons, and the contrast becomes sharpened with inereasing household size.
The comparative income distribution, among houscholds consisting of only one family, ${ }^{10}$ for households with one or more members aged 65 and over and for households without gainful workers, ${ }^{11}$ with unemployed heads, and with no employed gainful workers, is shown in table 7. The economic status of households with aged members is by far the best, especially as compared with those with uncmployed heads or without employed workers. The contrast would become even more striking if houschold size were taken into consideration, since the average number of members is almost twiee as great for households with unemployed hoads and with no employed workers as for households with aged members.

Tables 5, 6, and 7 substantiate the statement that, on the basis of available information on the relative conomic status of houscholds with aged members and certain other groups, households with aged members are economically far more secure as a group than are eertain other segments in the popuhation, such as houscholds with children,

[^5]those in which the head is a widowed, divorced, or separated woman; those in which the hoad is disabled or unemployed; those without gainful workers; and those without employed workers.

The income data used in this article relate to the latter part of 1934, 1935, and the carly months of 1936. Among the total aged population of some 8.4 million ${ }^{12}$ persons aged 65 or more, some 2 million aged persons are now receiving public assistance under the Federal-State old-age assistance program, and during January-June 1940 some 76,300 aged persons were allowed benefits under the old-age and survivors insurance provisions of the Social Sccurity Act. ${ }^{13}$ Only 800,000 of the estimated 36 million ${ }^{14}$ children under 16 years of age are bencfiting under the program for aid to dependent children, and during JanuaryJune 1940, claims for children's bencfits under oldage and survivors insurance were allowed for 18,400 children under 10. $\Lambda$ weekly average of more than a million unemployed workers are reeeiving unemployment benefits over restricted periods of time. Therefore, the relative economic security of the aged as contrasted with other elements in the population would seem greater now than at the time when the data for the family composition study were obtained. For other segments of the population, particularly for children and even more so for families in which the head of the family is disubled, there has been no significant improvement in relative economic security since these data were obtained.
