RECOMMENDATION

- tost

Based on results of water quality sampling FROM June 1986 through September 1989 it is recommended that the supplemental classification of nutrient sensitive waters be applied to the New River upstream from a line connecting Grey Point to a point of land approximately 2,200 yards downstream from the mouth of Duck Creek. This action will formalize the Director's previous use of NCAC, Title 15A: 2H.0404(c) in the New River. In addition it is recommended that the director use the following implementation strategy for nutrient controls such that the requirements of Title 15A: NCAC 2B .0214 (f), "Quality Standards Applicable to Nutrient Sensitive Waters (NSW)" are met:

- Nitrogen inputs should be initially controlled through the implementation of agricultural best management practices (BMPs) through the Agricultural Cost-Share program.
- Phosphorus inputs should be controlled through implementation of agricultural BMPs and point source reductions in phosphorus.
- 3) All existing wastewater facilities with a permitted design capacity of 0.05 MGD or greater should be given a 2.0 mg/l total phosphorus effluent limit (quarterly average of weekly samples) and have been notified they have until 1992 to achieve compliance with these new limits.
- 4) All new dischargers or expansions of existing discharges regardless of design capacity, will be required to meet the 2.0 mg/l total phosphorus limit when the new facility becomes operational.
- As required by North Carolina's antidegradation policy, Title 15A: NCAC 2B .0201(c), individuals considering a new discharge must demonstrate that nondischarge options or connection to an existing system are not feasible.
- 6) All facilities within the NSW area will be notified of the classification change and nutrient control strategies. They will also be notified that further (more stringent) controls on nutrient inputs may be required in the future.
- 7) The Division of Environmental Management (DEM) staff will continue to evaluate the eutrophication problems in the New River as well as any localized problems in the tributaries. In continuing the monitoring efforts, staff will attempt to identify any discharges (exempt from nutrient controls) which are having any localized impacts as a result of nutrient contributions and require appropriate control of nutrients on a case-by-case basis.
- The DEM staff will review success of the above strategy for nutrient controls in 1995 and recommend appropriate modifications at that time.

SUMMARY

The New River in Onslow County has been experiencing decreases in fish populations, increases in frequency of fish kills, discolored waters, low dissolved oxygen, and increasing abundance of algae. Based on these observations and the results of additional sampling in 1986, the director of DEM utilized NCAC, Title 15: 2H.0404 (c) to reduce nutrient inputs to the New River beginning January 1, 1987. This regulation states: "The Director may prohibit or limit any discharge of wastes into surface waters if, in the opinion of the Director, the surface waters experience or the discharge would result in:

- growths of microscopic vegetation such that chlorophyll-a values are greater than 40 ug/l; or
- (2) growths of microscopic or macroscopic vegetation which substantially impair the intended best usage of the waters."

Existing permits with allowed flows of 0.05 million gallons per day (MGD) or greater would receive 2.0 mg/l total phosphorus limits upon renewal. New permits and expansions would also receive 2.0 mg/l total phosphorus limits. Nitrogen controls were not addressed.

The use of the 0404 regulation to reduce the amount of phosphorus from point sources-was a positive step toward the control of nutrients and improvement of water quality in the New River. With complete implementation, the reduction of the phosphorus should have a noticeable impact on the amount of that nutrient available for phytoplankton growth.

DEM has continued water quality evaluations in the New River. This report presents the results for water quality sampling from June 1986 to September 1989. Conclusions from this report are as follows:

 Point source dischargers contribute 65 percent of the total phosphorus load and 49 percent of the total nitrogen load to the New River above Hadnot Point (based on export coefficients). Reduction of total phosphorus effluent concentrations to 2 mg/l is predicted to reduce point source total phosphorus contributions to less than 40 percent.

• Nutrient concentrations in the Wilson Bay area were high. Total nitrogen concentrations for the area averaged over 1 mg/l, with average total phosphorus concentrations of over 0.5 mg/l.

- Algal growth potential testing results from the Morgan Bay area just above Hadnot Point indicated that additions of nitrogen in that area could result in excessive algal growth and related water quality problems.
- Of the 180 chlorophyll-a samples collected between June 1986 and August 1989, 45 percent exceeded the state standard of 40 ug/l. In Wilson Bay, chlorophyll-a samples collected averaged over 100 ug/l and 88 percent exceeded the state standard for the period of this study.
- Chlorophyll-a concentrations, phytoplankton populations and nutrient concentrations in Wilson Bay were all high, indicating that the continued discharge by Jacksonville into Wilson Bay is severely degrading water quality and that efforts to relocate or remove the discharge should be expedited. The frequent violations of state standards indicate a need for widespread nutrient controls.
- Phytoplankton biovolume and density were elevated throughout most of the river. One hundred and twenty eight phytoplankton samples out of 180 for June 1986 through September 1989 had density and biovolume estimates indicative of bloom conditions (algal densities of 10,000 units/ml or greater and/or biovolumes of 5,000 mm³/m³).
- The extremely high levels of chlorophyll -a, the large amounts of algae represented by density and biovolume estimates, and the elevated nutrient concentrations even in the presence of massive algal populations are indicative of eutrophication. The numerous fish kills and the low dissolved oxygen levels, in association with the elevated chlorophyll-a levels, provide evidence that these growths of phytoplankton are impairing the best usage of the water.
- As the results from this study indicate, the New River in Onslow County is a highly eutrophic system above Hadnot Point. Continued pressure from the dischargers on the tributaries and the main stem of the river make it imperative that additional protection be afforded this area. The declaration of the New River as Nutrient Sensitive Waters in addition to limiting total phosphorus from point sources should encourage the targeting of cost share monies to Onslow County for nonpoint control of nitrogen inputs.

INTRODUCTION

The New River is a blackwater river located in the coastal plain in the White Oak River Basin. The entire New River watershed is within Onslow County, and above Jacksonville it is surrounded by gum-cypress swamps. As the river approaches Jacksonville, it widens and becomes significantly affected by tidal influences. Decreases in fish populations, increases in the frequency of fish kills, discoloration of the waters, low dissolved oxygen, and increases in the abundance of algae prompted the Wilmington Regional Office in 1986 to request an investigation of water quality in the Jacksonville area.

This investigation reviewed existing data from the ambient network, determined nutrient loading estimates from point and non-point sources and reviewed data collected during monthly sampling of the river and its tributaries during the summer of 1986. The study documented significant biological response to nutrient loading and the need for additional point source control of nutrients into the New River.

As a consequence, the director of DEM utilized NCAC, Title 15A: 2H.0404 (c), referred to in the rest of this report as 0404, to limit nutrient inputs. This regulation states: "The Director may prohibit or limit any discharge of wastes into surface waters if, in the opinion of the Director, the surface waters experience or the discharge would result in:

- growths of microscopic vegetation such that chlorophyll-a values are greater than 40 ug/l; or
- (2) growths of microscopic or macroscopic vegetation which substantially impair the intended best usage of the waters."

As of January 30, 1987, all new permit requests, and any expansion requests, within the New River Basin upstream from a line connecting Grey Point to a point of land approximately 2,200 yards downstream from the mouth of Duck Creek (Figure 1) received nutrient limitations of 2.0 mg/l phosphorus. Existing permits which have a permitted flow greater than 50,000 gallons per day (0.05MGD) are receiving the 2.0 mg/l phosphorus limitation in their renewed permits. This nutrient limitation applies to all dischargers located on main stem waters and tributaries to the New River upstream from the line of designation. This limit is similar to the management strategies used in the Neuse River Basin as a result of nutrient sensitive waters (NSW) designation.

Environmental evaluation continued on the New River system following this action to further document eutrophication problems and in response to increasing requests from developers, the City of Jacksonville, and Camp Lejune for new and increased discharges into the river and its tributaries.

-2-

This report reviews the actions and data taken in the New River Basin since 1986 and recommends possible actions for continued improvements of water quality within the watershed.

POINT SOURCES

Of the 45 point source dischargers permitted by the division within the New River Basin, 37 are located above Hadnot Point (near the mouth of Wallace Creek) where the majority of the water quality violations have been observed. A map and information on these dischargers are included in Appendix I and II. The combined permitted flow of these 37 dischargers is 11.1367 MGD. Approximately 40 percent of the permitted wasteflow in the upper portion is discharged to Wilson Bay. An additional 28 percent is discharged into the mouth of Northeast Creek.

Since the implementation of rule 2H .0404 in January 1987, five permits have been reissued with a phosphorus limit of 2 mg/l and two new permits have been issued with the 2 mg/l phosphorus limit (Table 1). There are 10 existing dischargers with a permitted flow greater than 0.05 MGD that will receive the 2 mg/l limit through permit renewal by 1992. The division has notified them that they will be required to meet the phosphorus limit by February 1, 1992.

NUTRIENT BUDGET

The nutrient budget developed for the New River grouped the loadings into point and nonpoint source categories (Appendix III). Nonpoint sources consisted of export from various land uses (forest, agriculture, wetlands and urban) and precipitation to the open water surface area. The Chowan/Albemarle Action Plan (NRCD 1982) provided the export coefficients for phosphorus and nitrogen loading rates and Table 2 lists that data and land use data for the New River. The estimated nonpoint source loads of total phosphorus (TP) and total nitrogen (TN) loads were 49,928 and 254,743 kg/yr, respectively.

Table 2. Nonpoint nutrient loading for the New River above Hadnot Point. Values based on 1987 landuse data obtained by the Wilmington Regional Office.					
LAND USE	AREA km ² (%)	P-LOADING RATE (kg/km ² -yr)	P-LOAD (kg/yr)	N-LOADING RATE (kg/km ² -yr)	N-LOAD (kg/yr)

TOTALS	719.0		49928		254743

Point source loads were determined using probable nutrient concentrations (5.3 mg/l TP and 17.4 mg/l TN) obtained from discharger self-monitoring data and permitted wasteflows. In 1987, 6.5 mg/l TP and 17.4 mg/l TN were used to calculate point source nutrient loading (Appendix III). Following the phosphorus ban which became effective in January 1988, it was determined that the TP load in the New River was reduced by approximately 18 percent (EHNR unpublished data); therefore 5.3 mg/l TP was used to determine point source loads (Table 3). The total estimated point source (at permitted conditions) TP and TN loads are 74,326 and 244,004 kg/yr, respectively.

Table 3. Point source nutrien point source flow is discharging as of Ja	t loading for the Ne the sum of the perr nuary 1, 1990.	w River above Hadno nitted flow for only th	ot Point. Total nose dischargers

Northeast Creek	3.148	23053	75673	
Wallace Creek	0.066	483	1599	
TOTALS	10.150	74326	244004	

-4-

A comparison of point source to nonpoint source loading indicates that point sources contribute approximately 60 percent of the TP and 49 percent of the TN to the system (Figure 2). This finding along with the nutrient and biological data presented in this report support the previously described point source controls of phosphorus. Nonpoint source control of nitrogen is encouraged to reduce that nutrient within this system.

STATION LOCATIONS

Station locations are shown in Figure 1 and station descriptions are provided in Table 4. Appendix IV indicates the classifications assigned to the New River and its tributaries sampled during this study. A total of seventeen stations were sampled during the period of June 1986 through August 1989. Samples were collected during June through September as these are the months during which nuisance phytoplankton blooms are normally reported in these waters. All samples were taken at midpoint of the river or tributary except in Wilson Bay where an extra station near the Wilson Bay Park was sampled. Stations that have been added and dropped during the past four years are indicated in Table 4. These changes were taken monthly during June through September with ambient stations also being sampled in the winter and spring months.

METHODS

A Hydrolab 4000 series multiparameter instrument was used to measure temperature, dissolved oxygen, pH, salinity, and conductivity. Quality control procedures, including pre and post calibration, were conducted in accordance with Standard Operating Procedures Manual, Physical and Chemical Monitoring (EHNR 1989). Depth profile measurements

-6-

were taken at 0.15 meters below the surface and at one meter intervals to the bottom. A Secchi disc was used to estimate the depth of light penetration. This device was lowered from the shaded side of the boat until it disappeared. It was then raised until it reappeared. The average between the two depths was considered the secchi value.

Nutrients (nitrogen and phosphorus), biological oxygen demand (BOD5), and fecal coliform samples were collected as grab samples. Samples were then tagged for identification and preserved as prescribed in the Procedures Manual, and transferred on ice to the Central Laboratory. Laboratory analyses were conducted according to the American Public Health Association (APHA) Standard Methods (APHA 1985).

Fresh aquatic macrophyte samples were used for identification (avoiding the collection of immature plants or those lacking flowers). All parts of the plant, including the roots, were taken for identification. After collection, the plant was wrapped in several layers of wet paper. The specimen and a completed sample identification tag were placed in a plastic bag and transferred on ice to DEM's Biological Assessment Group for identification to the lowest possible taxonomic level.

Phytoplankton and chlorophyll-a samples were also collected as grab samples. Phytoplankton samples were preserved using a modified Lugol's Solution. Identification and quantification methods employed were a modification of Utermohl's (1958) inverted microscope technique. This method is detailed in the <u>Biological Assessment Group's</u> <u>Standard Operating Procedures Manual</u> (EHNR 1990).

Statistical analysis was performed using StatView II software on a MacIntosh II computer. ANOVA analyses were used to determine significant differences for all parameters (except BOD, Secchi depth and fecal coliform) by years and stations. A significance level of 95 percent was used. Significant mean differences were not reported if the overall F test was not significant.

RESULTS AND DISCUSSION

PHYSICAL AND CHEMICAL

Rainfall and Flow. In July 1987 the USGS began collecting flow data at Gum Branch. Rainfall data was collected at Hoffman Forest for the entire duration of this study. A comparison of rainfall to flow indicated that the two sets of data followed each other closely enough for rainfall at Hoffman Forest to be useful as an estimation of inflow.

Figure 3 depicts the total monthly rainfall at Hoffman Forest. Mean rainfall for each month ranged from a low of 4.13 inches in 1988 to a high of 5.87 inches in 1989. The

-7-

next highest yearly mean was in 1987 with 4.77 inches. There was no significant difference (p>.05) in rainfall between years.

Heaviest rainfall occurred during July and August of all years, with less rainfall in the spring and winter. April 1989 was fairly wet with approximately eight inches of rainfall for the month. Rainfall in August and September 1989 was also relatively high.

Temperature. Surface water temperatures during the study ranged from 19°C to 34°C. Raw data for temperature and other parameters is presented in Appendix V. Figure 4 is a chart detailing the full distribution of the temperature data. The horizontal line crossing the box is the sample median or point at which 50 percent of the data falls above and 50 percent falls below. The notch around the median indicates the 95 percent confidence interval about the median, while the upper and lower ends of the boxes represent the 75th and 25th percentiles. This range provides a graphic indication of where the bulk of the data are distributed. The upper and lower whiskers indicate the 90th and 10th percentiles and the dots depict extreme values. During the summer growing season of June through September, the median surface water temperature was 27°C. The lowest summer temperatures were found at New River at Gum Branch (02093000), Southwest

Creek at Hwy 17 (SW1), and Little Northeast Creek at SR 1406 (0209317585). These three stations are shaded and relatively narrow when compared to the other wider, more open stations.

There was no strong thermal stratification on any of the sampling dates, as indicated by the differences between top and bottom temperatures of less than or equal to 2°C.

Dissolved Oxygen. Surface dissolved oxygen (DO) values ranged from 2.5 to 18.6 mg/l with percent saturation from 29 to greater than 200 percent. Low DO concentrations occurred in Southwest Creek at Highway 17 (SW1), where three out of four DO concentrations were at or below 5 mg/l and saturation was from 39 to 61 percent. Southwest Creek is a slow-moving blackwater stream with a depth of approximately one meter at the sampling point. Low DO concentrations (surface concentrations less than 5 mg/l) were also present near the mouth of Southwest Creek (SW2). The combination of high organic content usually associated with blackwater systems and low flow probably resulted in the low DO concentrations measured at these stations.

Most of the other low DO concentrations were taken at tributary stations (Figure 5). During 1986 and 1989, DO concentrations at Highway 17 on the New River (02093032) were below 60 percent saturation throughout the water column during June through September. The station was well mixed with low salinities except on July 30, 1986, when

-9-

the bottom salinity was 16 parts per thousand (ppt). Total monthly rainfall at Hoffman Forest for July 1986 was 10.17 inches, one of the highest totals during the study period. Freshwater inflow from the low DO blackwater upper reaches of the river may have resulted in these low DO concentrations. Sampling in 1985 above the Highway 17 bridge indicated depressed DO levels as close as the mouth of Blue Creek (approximately one mile above Highway 17).

Dissolved oxygen profiles for the river stations showed DO concentrations following a clinograde curve during most of the sampling period with sharply decreasing DO concentrations below two meters. Profiles for August 29, 1989, shown in Figure 6 were typical of the dissolved oxygen profiles for the sampling period. Salt wedges contribute to the low bottom DO concentrations by creating a density gradient between the low and high salinity waters. This gradient slows mixing between the more oxygenated surface waters and the bottom waters. As a result, biochemical reactions in the bottom waters and at the sediment interface deplete DO concentrations.

There were no significant differences (p>0.5) between stations and although DO concentrations appeared to be higher at the Highway 17 bridges, there were no significant differences (p>0.5) between the river stations above or below Morgan Bay.

-11-

pH. Surface pH measurements ranged from 5.5 to 9.1 standard units (SU) with a average of 7.7 SU. The measurement of 5.5 SU was made at Gum Branch (02093000) on July 20, 1987. Organic discharge from the Richlands WWTP could result in lowered pH values at this site. The elevated pH values made in Wilson Bay (WB05) were probably due the increased algal activity in the area of the City's discharge.

Average pH values for the river stations were highest from the New River between Southwest and Northeast Creeks (NR) down to Sneads Ferry (Figure 7). These values were within the state standard of 6.8 to 8.5 SU for tidal waters.

Conductivity and Salinity. Conductivity and salinity measurements indicated that salt wedges extended to the 17/24 bridge. Data collected in 1985 indicated that salt wedges occur as far upstream as Tar Landing which is approximately six miles upstream of the 17/24 bridge. Salt wedges were present at all river stations except during high or steady winds and rain events. These two factors resulted in mixing throughout the water column. In May 1986 salt wedges occurred in the tributaries with a wedge reaching as far up Northeast Creek as Little Northeast Creek, which is approximately four miles from the mouth of Northeast Creek.

Salinities were significantly higher at Sneads Ferry (02093197), the station closest to the Atlantic Ocean (Figure 8). Surface salinities ranged from 11 to 26 ppt at this station.

No significant differences (p>0.5)were found in conductivity or salinity between

years.

Secchi Depth and Turbidity. Secchi depth measurements ranged from 0.2 to 1 meter during June through September (Figure 9). Lowest Secchi depth measurements were found in Wilson Bay at the Park (WB05) and in Northeast Creek at Hwy 24 with highest values near Hadnot Point (NR2). Turbidity readings were also elevated at this station (Figure 9) although not above the state standard of 25 NTU.

Only two turbidity values were above the state standard of 25 NTU during this study, from Gum Branch. On July 13, 1988, turbidity was 50 NTU and, on June 27, 1988, it was 32 NTU. No secchi depth readings were taken at this station. Chlorophyll-a concentrations were low (8 and 10 ug/l) indicating that algal activity was not contributing to the high turbidity. Rainfall the day before and on the day of sampling probably resulted in increased turbidity.

-13-

Both Wilson Bay and Brinson Creek had shallow Secchi depths due to their shallow depths (average = one meter) and very murky sediment which is easily disturbed by wind action. Wilson Bay also had the highest chlorophyll-a concentrations and phytoplankton populations indicating that phytoplankton probably contributed to the reduced Secchi depths although the turbidity values in Wilson Bay and Brinson Creek were not significantly elevated.

There appeared to be a slight decrease in turbidity and an increase in Secchi depths as the stations progressed downstream. Deepest Secchi depths and lowest turbidity readings were found near Hadnot Point. Downstream of Hadnot Point Secchi depths decreased and turbidity increased due to tidal influences and increased salinity.

NUTRIENTS

Nitrogen. Within the New River highest average concentrations of nitrogen during June through September were found at Gum Branch (02093000) during 1987 (Figure 10). This area is highly agricultural with fields extending to the river banks in many areas. There are two permitted dischargers above this station. Carter Packing (NC0002968) discharged above this station until its permit was rescinded due to violations of its BOD5, total suspended solids and nitrogen effluent limits. This operation ceased discharging in August 1987. Richlands WWTP's discharge (NC0023230) is also located above Gum Branch on Mill Swamp. Self-monitoring data for both dischargers is contained in Table 5. Richlands WWTP had the highest contribution of nitrogen to the system with average total nitrogen (TN) concentrations ranging from 6.12 to 16.30 mg/l. Both ammonia/ammonium (NH₃/NH₄) and TN concentrations in Richlands discharge decreased in 1989. These decreases were accompanied by decreases in flow out of the plant and decreases in nitrogen at Gum Branch.

Downstream, highest nitrogen values were recorded in Wilson Bay (WB05 & WB50) and Brinson Creek (BC). Wilson Bay receives discharge from the City of Jacksonville Wilson Bay WWTP (NC0024121). This plant has had overflows and frequent violations

-

of its permit limits. Dye work completed in 1987 documented a long retention time and limited water circulation patterns within the bay, and indicated that tidal variations were not effective in flushing the bay. As a result of these conditions, Wilson Bay is highly eutrophic with sufficient nitrogen concentrations to support bloom phytoplankton populations year round (Figure 11).

Nitrogen concentrations in the lower New River from marker 50 down to Sneads Ferry were lower than in the upper river with NO2/NO3 below detection in 88 percent of the samples.

No significant differences were found between years for nitrogen.

Phosphorus. Phosphorus concentrations were elevated from Gum Branch to Wilson Bay and decreased downstream to Sneads Ferry (Figure 12). Highest concentrations were

seen in Wilson Bay during 1987 when PO₄ concentrations averaged 0.60 mg/l and TP concentrations averaged 0.85 mg/l. The threshold concentration of PO₄ for algal growth is 0.05 mg/l and the minimal concentration for TP is 0.1 mg/l. Phytoplankton populations reflected this abundance of nutrients with average biovolumes of 13,619 mm³/m³ and densities of 319,444 units/ml. Bloom conditions are considered to exist when phytoplankton biovolume reaches 5,000 mm³/m³ and/or density reaches 10,000 units/ml.

Tributary stations had higher concentrations of phosphorus compared to stations located below Wilson Bay (marker 50). Values for Morgan Bay and Sneads Ferry were lower than in the tributaries.

There appeared to be a slight decrease in phosphorus concentrations at all stations in 1989. ANOVA results indicate that TP and PO₄ were significantly lower in 1989 than in 1987; however, there was no significant difference between other years. Several factors may have contributed to this decrease. Rainfall in 1989 was slightly higher during the sampling period. In 1987 the Clean Detergent Act was initiated which banned the use of phosphate detergents and cleaning agents throughout the state. No clear indication of the decrease was evident in a review of self-monitoring data. An in-depth review of self-monitoring data would be necessary to discern the presence of any differences before and after the Clean Detergent Act. This was not performed as part of this study.

BIOLOGICAL DATA

1

Biochemical Oxygen Demand. Biochemical oxygen demand (BOD) provides an estimate of the amount of oxygen being utilized by biological and chemical processes within the water column. Five day BOD readings were used in this study. Values ranged from 0.6 to 13 mg/l with an average of 4.1 mg/l for all stations. Highest BOD readings were obtained at Wilson Bay and Brinson Creek (Figure 13). The average concentrations for Wilson Bay at WB05 was 12 mg/l and at WB50 the average was 8.5 mg/l. The average concentration for Brinson Creek was 8 mg/l. All other stations had values below 6 mg/l except for a few outliers. The high BOD values for Wilson Bay and Brinson Creek reflect the amount of effluent in each area. Brinson Creek has a 7Q10 of 0.05 MGD and has five permitted dischargers with permitted flows totaling 0.24 MGD. Actual discharge into Brinson Creek is approximately 0.07 MGD according to self-monitoring data. This is still above the stream's 7Q10 (1.4 times greater). Wilson Bay receives 4.46 MGD discharge from the Wilson Bay WWTP. Problems with the plant have resulted in a large buildup of sludge in Wilson Bay increasing BOD (DEM unpublished data).

Downstream from Wilson Bay there was little difference in BOD except in Southwest Creek at Hwy 24 (SW1) and Little Northeast Creek (0209317585). BOD at these stations was lower than other stations with concentrations of 0.5 to 2 mg/l, respectively.

Fecal Coliform Bacteria. Fecal coliform bacteria are used as a likely indicator of the presence of other harmful bacteria in surface waters. Most fecal coliform values in the New River were below the state standard of 200 membrane filter fecal coliform colonies(MFFCC)/100ml (Figure 14) with highest values found in the tributaries. Most of the high concentrations below Gum Branch were associated with rain events indicating that nonpoint sources were the primary cause for the elevated levels.

Wilson Bay was an exception to this as concentrations in 1988 and 1989 were consistently above 200 MFFCC/100ml. Concentrations in Wilson Bay ranged from 150 to 6,800 MFFCC/100ml during 1988 and 1989. These concentrations are a result of operational problems at Jacksonville's Wilson Bay WWTP. As a result of these and other state standard violations, Jacksonville will be closing this treatment plant and is in the process of designing a new WWTP. DEM staff have recommended that the plant be nondischarge due to the nutrient sensitive nature of the New River around Jacksonville.

Aquatic Macrophytes. Samples collected from the New River above Tar Landing in 1985 indicated that alligatorweed (Alternanthera philoxeroides) was present in abundance in the river basin. This macrophyte may be found free-floating, loosely attached and forming mats, rooted, emersed, or in a dry field. Alligatorweed prefers fresh, highly fertile water, but will tolerate brackish water to 30 percent sea water. Dense mats of this weed interfere with navigation, recreational water uses, increase sedimentation, and reduce the drainage capacity of canals and streams which can result in flooding.

Alligatorweed, essentially confined to the coastal plain, is widespread and locally abundant in the Alligator, Cape Fear, Little, Lumber, New, Pasquotank, Perquimans, Scuppernong, Tar, and Waccamaw Rivers. Of the forty-five coastal plain counties, twenty-nine reported alligatorweed infestations (Langeland 1986). The major impact in the study area is the upper narrow reaches of the New River, Half Moon and Blue Creeks, and

-21-

Chaney and Mill Creeks, tributaries to the New River located in Jacksonville. As part of the Division of Water Resources Aquatic Plant Control Program, several small plots of alligatorweed (less than five acres) have been treated with Rodeo in Chaney and Mill Creeks in the past three years.

Chlorophyll-a and Phytoplankton Biovolume and Density. Chlorophyll-a concentrations during the four year study ranged from <1 to 310 ug/ml. Twenty eight of fifty two (54%), 26 of 52 (50%), 16 of 47 (38%), and 11 of 29 (38%) of the chlorophyll-a samples analyzed in 1986, 1987, 1988, and 1989 respectively were above the state standard of 40 ug/l. The apparent decrease in the number of violations is probably due to a shift in emphasis from the Morgan Bay area to the lower river stations in 1988 and 1989. Values from Wilson Bay (stations WB05 and WB50) averaged over 100 ug/ml and 88 percent of the samples were above the standard for the period of study. Maximum levels of 260 and 310 ug/ml occurred at WB05 in July 1986 and June 1987 respectively (Figure 15). Wilson Bay receives discharge from Jacksonville's WWTP, which has a permitted flow of 4.46 MGD. The slow flushing rate found in Wilson Bay contributes to the eutrophication problems experienced there by increasing the retention time in the bay. The nutrient concentrations remained very high in this section of the river even in the presence of bloom level phytoplankton populations.

Figure 15 depicts the monthly (June-September) chlorophyll-a values measured in the New River. Measurements taken at Wilson Bay and upstream consistently ranged above the 40 ug/l standard while the stations located below Wilson Bay rarely exceeded the limit. These differences may be due in part to the higher concentration of the dischargers from Wilson Bay upstream and in part due to the greater dilution in the lower reaches where the river is much wider and tidal influences are greater.

The following classes of algal were represented in samples collected from the New River: cryptomonads (Cryptophyceae), diatoms (Bacillariophyceae), greens (Chlorophyceae), chrysophytes (Chrysophyceae), dinoflagellates (Dinophyceae), euglenoids (Euglenophyceae), and yellow greens (Xanthophyceae). Dominant algal classes representing more than 20 percent of the biovolume are presented in Figure 16. Diatoms, dinoflagellates, and chrysophytes were the dominant classes during most of the summer. These classes are normally dominant in brackish waters.

Of the total 180 phytoplankton samples collected for quantitative analysis, 110 samples contained either elevated algal biovolumes or densities. Thirty-six of these samples were collected from the New River, 35 came from Wilson Bay, and the remaining 39 samples were collected from the tributaries.

1

-24-

Station 02093000 (Gum Branch) is located 15 miles upstream of Wilson Bay, is more riverine, especially during periods of high flow, and is less likely to exhibit elevated levels of algal activity. As depicted in Figure 17, the average values for this station are well below those exhibited at any other station. Chlorophyll-a values averaged less than 7 ug/l and phytoplankton biovolumes were dominated (comprising more than 20 percent of the total biovolume) by <u>Tabellaria fenestrata</u> (Bacillariophyceae) and <u>Micractinium pusillum</u> (Chlorophyceae). The sample from September 1988 was dominated by <u>Cryptomonas</u> <u>erosa</u> (Cryptophyceae).

Station 02093032 (Highway 17/24 bridge) is approximately three miles upstream of Wilson Bay and experiences slight tidal influence. Phytoplankton density and biovolume from this station in June were dominated by <u>Cyclotella</u> species 2, <u>Skelotonema costatum</u>, and <u>Tabellaria fenestrata</u>. These three diatom species made up 75 percent of the biovolume and over 80 percent of the algal density. <u>Cyclotella</u> species 2 and <u>Skelotonema costatum</u> are often found in estuarine systems and are common to the lower Neuse and Pamlico River Basins.

In 1986, <u>Cyclotella</u> species 2 comprised 55 percent of the biovolume and in 1987 the dinoflagellates, <u>Gymnodinium aurantium</u> and <u>G</u>. species 2 dominated 85 percent of the algal biovolume. The Xanthophyte, <u>Olisthodiscus carterae</u>, contributed 86 percent and the Euglenophyte, <u>Lepocinclis</u> species 3 comprised 70 percent of the 1988 and 1989 algal biovolume, respectively. These three species, along with <u>Gymnodinium nelsoni</u> were co-dominant in August and September for all four years.

The two stations located in Wilson Bay, WB05 and WB50, were dominated by diatoms (Bacillariophyceae). <u>Cyclotella</u> species 2 was the major dominant algae and comprised at least 50 percent and in several cases over 90 percent of the total biovolume. This small centric diatom is apparently able to outcompete other species in this highly eutrophic bay and attain elevated population levels. Yearly averages for algal biovolume, density and chlorophyll-a content all corresponded well for these two stations (Figure 17). The small size of these diatoms is evident when density estimates were compared to biovolume estimates. For example, a density of 500,000 units/ml at WB05 in July 1988 had a biovolume of only 12,000 mm³/m³. <u>Gymnodinium aurantium</u> and <u>G</u>. species 4, along with <u>Chroomonas caudata</u> (Cryptophyceae), were also dominant at these stations.

の問題

Biovolume estimates at NR, located downstream of the Wilson Bay area between the mouths of Northeast and Southwest Creeks, were dominated by <u>Cyclotella</u> species 2. <u>Gymnodinium aurantium</u>, <u>G</u>. species 4, and <u>Gyrodinium aureolum</u> dominated the 1988 samples and again in July 1989.

-25-

-

Stations NR 1, NR 2, AND NR 3 are located farther downstream and were only sampled in 1989. Domination of phytoplankton at these stations varied between Gymnodinium aurantium, Gyrodinium aureolum, Oxyrrhis marina, Prorocentrum minimum, common estuarine dinoflagellates, and Dictyocha fibula (Chrysophyceae).

<u>Skelotonema costatum, Nitzschia closterium, N.</u> species, and <u>Rhizosolenia</u> <u>stolterfothii</u> were the dominant diatoms at 02093197 (Sneads Ferry) due to their euryhaline nature. These algae were responsible for at least 40 percent of the biovolume in July and September of 1987, June of 1988, and June and July of 1989. <u>Chroomonas amphioxeia</u> and <u>Cryptomonas ovata</u> (Cryptophyceae) made up 50 percent of the biovolume in August and September of 1988. <u>Ceratium species</u>, <u>Peridinium trochoideum</u>, and <u>Oxyrrhis marina</u> were the dominant species in July and August 1988. <u>Peridinium trochoideum</u> and <u>Gymnodinium</u> species 4 dominated samples from June and August 1989.

Algal populations at the mouths of the tributaries were similar to the New River assemblages. Brinson Creek (BC) exhibited elevated levels of phytoplankton several times in the study period. Nutrient concentrations were also elevated at this station. A chlorophyll-a value of 220 ug/l was recorded from July 1986 when <u>Cyclotella</u> species 2 made up 97 percent of the biovolume. This species also played an important part in the composition of the phytoplankton populations of Northeast, Southwest, and Wallace Creeks.

Species composition, extremely elevated levels of chlorophyll-a, nuisance phytoplankton populations during the growing season in combination with the continued presence of high nutrient concentrations indicate that this area is very eutrophic and nutrient controls are warranted.

Algal Growth Potential Test. Algal growth potential tests (AGPT) provide information on capacity of a water body to support nuisance algal populations and determine which nutrient may be responsible for limiting algal growth (USEPA 1978). In order to perform this test, water is collected, autoclaved, and filtered. Samples are then treated separately with additions of nitrogen and/or phosphorus. When the added nutrient results in an increase in mean standing crop (MSC) over the control, that nutrient is said to be limiting to phytoplankton growth, indicating that increases of the limiting nutrient to the water body could result in nuisance algal populations. A MSC of 5 mg/l or less generally is a level that will not promote excessive algal growth. MSC exceeding 10 mg/l are associated with highly productive waters which may be subjected to nuisance algal blooms and fish kills

In June 1989, AGPT's were performed for DEM by the United States Environmental Protection Agency Region IV personnel on samples collected from three stations in the New River. The stations were located above, in, and below Morgan Bay. This area was chosen as Jacksonville was contemplating moving their Wilson Bay discharge to this area.

The results indicate that the addition of nitrogen to the samples greatly increases algal production (Table 6). Little change occurred to any samples when phosphorus was added indicating that phosphorus is already present in sufficient quantities to support algal growth. Data from the control samples indicated that NR50, located in the middle of Morgan Bay, can already achieve a MSC above the 5 mg/l lower level without any addition of nutrients. Therefore existing conditions at this station are favorable for algal blooms.

The reduction of phosphorus as outlined in the NSW recommendations would drive the system toward phosphorus limitation. This would theoretically reduce the control MSC and reduce the phytoplankton levels and the likelihood of nuisance blooms.

DIVISION OF ENVIRONMENTAL MANAGEMENT

January 30, 1987

MEMORANDUM

United and a second

TO:

FROM:

George T. Everett Chuck Wakild R. Paul Wilms

SUBJECT:

Point Source Nutrient Limitations, New River Onslow County, N.C.

I have completed my review of the report prepared by the Water Quality Section concerning the New River in Onslow County. The data and evidence strongly supports the need for additional point source control of nutrients into these receiving waters.

Therefore, based upon the evaluation of data, it is the position of this office that regulations NCAC, 15: 2H.0403 and 2H.0404(c) are clearly appropriate to address this situation.

NCAC, Title 15: 2H.0404(c) states: "The director may prohibit or limit any discharge of wastes into surface waters if, in the opinion of the director, the surface waters experience or the discharge would result in:

- growths of microscopic vegetation such that chlorophyll <u>a</u> values are greater than 40 ug/l; or
- (2) growths of microscopic or macroscopic vegetation which substantially impair the intended best usage of the waters."

Therefore, effective immediately, the staff should include appropriate nutrient limitations (2.0 mg/l total phosphorous) in all new permit requests and any expansion requests within the New River Basin upstream from a line connecting Grey Point to a point of land approximately 2200 yards downstream from the mouth of Duck Creek. This applies to all main stem waters and tributaries to the New River upstream from this line of designation.

Upon expiration of existing permits which have a design flow greater than 50,000 gallons per day, the same nutrient effluent limitation of 2.0 mg/l phosphorous should be applied to the reissued NPDES permits.

cc: Steve W. Tedder Preston Howard

NEW RIVER BASIN

ONSLOW COUNTY

APPLICATION OF COASTAL REGULATION 2H.0404(C)

Division of Environmental Management

Water Quality Section

January 1987

INTRODUCTION

The New River is a blackwater river surrounded by gum-cypress swamp above Jacksonville where the River broadens and becomes significantly affected by tidal influences. Reports of decreases in anadromous fish populations, increasing frequency of fish kills, discoloration of waters, and low dissolved oxygen in the New River prompted the Wilmington Regional Office to request an investigation to assess water quality in the Jacksonville area.

This investigation included review of existing data in the ambient network, estimates of nutrient loading from point and non-point sources, and monthly sampling in the New River and its tributaries during the summer of 1986.

The results of this investigation documented an alarming biological response to current nutrient loading into the New River. The following information summarizes those results and recommends possible actions to improve water quality in the New River watershed.

FIGURE 1. STATION LOCATIONS FOR THE NEW RIVER.

-37-

BACKGROUND

Problems associated with the over-enrichment of surface waters have been identified in many areas of North Carolina in recent years. These problems are most obvious in fresh waters experiencing advanced stages of eutrophication. Surface scums of blue-green algae and subsequent fish kills have occurred, on the Chowan River in 1972 and Neuse River in 1983.

While having the potential of being just as harmful, overenrichment in estuarine waters is more subtle in appearance. Staff of the Wilmington Regional Office observed impacts often associated with over-enrichment occurring frequently over past years in the New River estuary and its tributaries near Jacksonville, North Carolina. Sixteen fish kills have been documented in the area since 1978. Some of these kills were attributed to sewer overflows and others to low dissolved oxygen concentrations as a result of algal blooms.

Problems in the late summer of 1985 were frequent and rather extensive (Table 1). Fish kills occurred in Northeast Creek, Wilson Bay, and as far upstream as Tar Landing on the New River in August and September. Low dissolved oxygen concentrations (<4 mg/l) and high chlorophyll-a concentrations (300 ug/l) were associated with these kills. With these increased problems, the Regional Office requested the assistance of the Technical Services Branch to assess the extent and potential impacts of over-enrichment- in this area.

A survey was conducted October 3, 1985 on the New River from Jack's Point upstream to a point above Tar Landing where further progress was impeded by a dense mat of alligator-weed (<u>Alternanthera philoxeroidos</u>). Low dissolved oxygen concentrations were measured in the surface waters at 7 locations near and above the Hwy 17/24 bridge at Jacksonville. High nutrient and chlorophyll-a concentrations were measured near Wilson Bay. As a result of data review, it was determined that more intensive monitoring in the Jacksonville area would improve assessment of water guality conditions in the area

CONCLUSION - STRONG EVIDENCE OF SEVERE ENRICHMENT PROBLEMS IN TRIBUTARIES AND IN NEW RIVER NEAR JACKSONVILLE.

Monthly sampling was initiated in 1986 in the New River and major tributaries near Jacksonville (Figure 1) Measured parameters included nutrients, chlorophyll-a, and phytoplankton concentrations, as well as physical data (conductivity, dissolved oxygen, temperature and salinity), and BOD₆ and fecal coliform.

Point Sources

There are a total of forty-three point source discharges permitted by the Division within the New River Basin. Of these forty-three discharges, thirtyfive are built and discharging to waters of the basin. Thirty existing discharges are located upstream of Hadnot Point (near mouth of Wallace Creek) in the upper basin where the majority of water quality violations have been observed. The combined wasteflow of these latter thirty discharges totals 10.2 MGD.

Approximately 60 percent of the permitted wasteflow in the upper New River Basin is discharged to Wilson Bay. Another 31 percent is discharged into the mouth of Northeast Creek. Numerous small discharges (0.001 to 0.100 MGD) are located along tributaries throughout the upper basin.

Nutrient Budget

Preliminary nutrient budgets have been developed for the upper New River Basin (above Hadnot Point) for total phosphorus (TP) and total nitrogen (TN). Nutrient loads were grouped into point source and non-point source categories. Non-point sources consisted of export from various land uses (i.e. forest, agriculture, wetlands, and urban) and from precipitation to the open water surface area.

Non-point source loads were estimated using nutrient export coefficients and land use data provided by the Wilmington Regional Office (Table 2). The export coefficients (i e p-loading rate, n-loading rate) were obtained from the Chowan/Albemarle Action Plan (NRCD, 1982). The total estimated non-point source TP and TN loads are 49930 kg/yr and 254745 kg/yr, respectively.

Upper New River Basin Nutrient Budgets

EXISTING TOTAL PHOSPHORUS LOAD

EXISTING TOTAL NITROGEN LOAD

-42-

Point source loads were estimated using probable nutrient concentration ranges obtained from basin-pooled self-monitoring data (performed for Neuse River and Tar/Pamlico River studies) and permitted wasteflows (Table 3). Wasteflows were totaled for various basin segments; and then multiplied by 6.5 mg/l TP and 17 4 mg/l TN to determine point source loads. These concentrations reflect the midpoints of the likely ranges of TP, 5.0 to 8.0 mg/l, and TN, 14.8 mg/l to 20 mg/l. Loading estimates which reflect the ranges are shown in parentheses below the average estimates in Table 3. The total estimated point source (at permitted conditions) TP and TN loads are 91,735 kg/yr and 245,580 kg/yr.

The estimated point source phosphorus load is nearly twice that of the non-point source estimate, accounting for 65 percent of the total basin load (Figure 2). The expected nitrogen contribution from point sources is expected to be about equal to the non-point source TN load (Figure 2). These substantial contributions from point sources to the overall nutrient load have led to elevated nutrient concentrations within the New River Basin.

RESULTS OF 1986 SUMMER SURVEY

River Sites

Sampling included 6 sites on the New River from Gum Branch to Sneads Ferry. Mean values of nutrient, chlorophyll-a and phytoplankton data are presented in Table 4 and the corresponding distributions are shown by station location in Figures 3, 4 and 5.

It should be noted that nutrient values at Gum Branch were elevated (mean TP=0.3 mg/l) and tended to increase during periods of low flow, which generally indicates point source impacts. Problems were identified with effluent discharges from Carter Packing Company. A total of 48 effluent violations (see attached) were found during a 23 month period. Therefore, Gum Branch would not serve as a representative upstream "background level" location.

1

-43--

Downstream, total nitrogen was relatively high (>1 mg/l) at Highway 17/24 near Jacksonville, increased dramatically at Wilson Bay, and gradually declined to more desirable concentrations at Sneads Ferry which is about 30 miles downstream of Gum Branch and is very near the Atlantic Ocean. 101 belator 2000

Mean concentrations of total phosphorus displayed a similar pattern in a downstream progression Relative concentrations were not as elevated as nitrogen at Gum Branch, but were extremely high near Wilson Bay.

Chlorophyll-a and phytoplankton analyses revealed a tremendous response to over-enrichment in the Jacksonville area. Mean chlorophyll-a concentrations from the Hwy 17/24 bridge to Station NR 50% (New River at mid channel near the mouths of Northeast and Southwest Creeks ranged from 48-165 ug/l (Figure 5)

It should also be noted that dominance by a single group of organisms was responsible for most of the measured chlorophyll-a concentrations in the Wilson Bay area. Those phytoplankton present were not surface, scum forming, species as seen in our freshwater rivers, but were found in concentrations large enough to severely affect dissolved oxygen in shallow areas. This type of uni-algal dominance is not generally healthy to most food webs (Figure 6).

Tributary Sites

Mean concentrations of chlorophyli-a, nutrients, and phytoplankton for major tribularies to the New River near Jacksonville are presented in Table 5. Brinson Creek was sampled near the mouth only. Chlorophyll-a concentrations at this site exceeded the water quality standard each date sampled and the mean value was 103 ug/l. Little Northeast, which flows into Northeast Creek, also contained chlorophyll-a values well above the standard.

Chlorophyll-a standard exceedances were also identified at the mouths of Northeast, Brinson, Southwest and Wallace Creeks (Figure 7) The only sites sampled during the survey that did not seem to be experiencing significant effects from overenrichment were the most upstream sites on Wallace and Southwest

Creeks.

Conclusions

Current nutrient loading into the New River and its tributaries near Jacksonville, N.C. are significantly impacting water quality as indicated by the following:

- Almost 60% of chlorophyll-a samples taken during a survey in the New River and the mouths of Brinson, Little Northeast, Northeast, Southwest and Wallace Creeks from June-September 1986 exceeded 40 ug/l.
- Phytoplankton biovolumes measured during this time period often exceeded
 5,000 mm³/m³ with uni-algal dominance by certain phytoplankton.
- Phytoplankton density as high as 813,000 units/ml were measured in Wilson Bay. A density of 100,000 units/ml is considered a "bloom" by any phytoplankton ecologist.

The numerous fish kills and low dissolved oxygen levels, in association with highly colored water and elevated chlorophyll-a levels during the past few years provide strong circumstantial evidence that growths of microscopic vegetation substantially impair the intended best usage of the waters.

NEW RIVER SUMMARY & RECOMMENDATIONS

Based upon the data and evidence available, it is a staff recommendation is that the Director exercise his authority as provided in NCAC. Title, 15:, 2H, 0404 which addresses facility location and design involving coastal waste treatment disposal.

NCAC, Title 15: 2H.0404(c) states: "The director may prohibit or limit any discharge of waste into surface waters if, in the opinion of the director, the surface waters experience or the discharge would result in:

- growths of microscopic vegetation such that chlorophyll <u>a</u> values are greater than 40 ug/l; or
- (2) growths of microscopic or macroscopic vegetation which substantially impair the intended best usage of the waters.

NCAC, T15: 2H.0403 clearly incorporates the New River and its tributaries, as far as applicability of these regulations to the waters in question.

It is the staff's recommendation that the Director determine appropriate nutrient limitations for all new or expanding discharges in this system, as opposed to prohibition of discharge. Currently there are 43 permitted discharges in the area. At this time there are four (4) proposed applications and one (1) proposed expansion. Implementation of .0404(c) therefore would immediately only impact (not prohibit) five proposed actions.

There exist two viable options for facilities which currently hold issued NPDES permits. The first option would be to petition the EMC to exercise its authority relating to the classification of waters. As detailed in NCAC, T15: .0214, the EMC may designate and classify these waters as nutrient sensitive (NSW).

A second option would be for the Director to apply 0404(c) to each existing facility upon expiration of the existing NPDES permits

- 54-

Both of these options would necessitate nutrient limitations to be incorporated into final permit limitations either basin-wide or case-by-case.

Based upon available data and knowledge, the staff would recommend the same nutrient limitations that will be applied to the Falls and Jordan NSW basin strategy.

Effectiveness of Controls

影子。

Since point sources account for a major portion of nutrient loading to the New River Basin, Point source controls will provide an effective means of reducing elevated nutrient levels. If a 1.0 mg/l monthly average phosphorus limit were placed on existing discharges, an estimated 85 percent reduction in point source loading could be achieved. The contribution of point source phosphorus loading to the upper basin would be reduced from the existing level of 65 percent to 22 percent (Figure 8). The corresponding reduction in overall phosphorus mass would be approximately 76,600 kg/yr (55 percent), from 141,665 kg/yr to 64,045 kg/yr (Figure 9).

If a 2.0 mg/l monthly average phosphorus limit were applied, an estimated 69 percent reduction in point source loading could be achieved. The point source contribution to the basin would be reduced to 36 percent (Figure 10). The corresponding reduction in overall phosphorus mass would be approximately 62,500 kg/yr (45 percent), from 141,665 kg/yr to 78,160 kg/yr (Figure 11).

DIVISION OF ENVIRONMENTAL MANAGEMENT

June 3, 1987

MEMORANDUM

TO: Dennis Ramsey Steve W. Tedder Alan Klimek Preston Howard

Seorge V. Evere

FROM: George T. Everett

SUBJECT:

Point Source Nutrient Limitations, New River Onslow County, N.C.

By correspondence dated January 30, 1987, the Director determined that NCAC, Title 15: 2H.0404(c) was applicable to the New River in Onslow County (see attached).

It has come to my attention that additional clarification of the January 30, 1987 directive may be needed. Effective January 30, 1987, the staff was instructed by the Director to include appropriate nutrient limitations in all new permit requests and any expansion requests within the New River Basin upstream from a line connecting Grey Point to a point of land approximately 2200 yards downstream from the mouth of Duck Creek. This applies to all main stem water and tributaries to the New River upstream from this line of designation.

The nutrient limitations to be included are 2.0 mg/l total phosphorous, with compliance to be determined as a quarterly average based upon weekly data collection.

These limitations are to be applied to all discharges with a design flow of 50,000 gpd and greater.

If there are questions, please contact.

cc: Arthur Mouberry Dale Overcash Trevor Clements

DIVISION OF ENVIRONMENTAL MANAGEMENT

January 30, 1987

MEMORANDUM

-	George T. Everett	
10.	Chuck Wakild	-
	D Davil Wilms /	1

FROM: SUBJECT:

Point Source Nutrient Limitations, New River Onslow County, N.C.

I have completed my review of the report prepared by the Water Quality Section concerning the New River in Onslow County. The data and evidence strongly supports the need for additional point source control of nutrients into these receiving waters.

Therefore, based upon the evaluation of data, it is the position of this office that regulations NCAC, 15: 2E.0403 and 2H.0404(c) are clearly appropriate to address this situation.

NCAC, Title 15: 2H.0404(c) states: "The director may prohibit or limit any discharge of wastes into surface waters if, in the opinion of the director, the surface waters experience or the discharge would result in:

- growths of microscopic vegetation such that chlorophyll a (1) values are greater than 40 ug/1; cr
- (2) growths of microscopic or macroscopic vegetation which substantially impair the intended best usage of the waters."

Therefore, effective immediately, the staff should include appropriate nutrient limitations (2.0 mg/l total phosphorous) in all new permit requests and any expansion requests within the New River Basin upstream from a line connecting Grey Foint to a point of land approximately 2200 yards downstream from the mouth of Duck Creek. This applies to all main stem waters and tributaries to the New River upstream from this line of designation.

Upon expiration of existing permits which have a design flow greater than 50,000 gallons per day, the same nutrient effluent limitation of 2.0 mg/l phosphorous should be applied to the reissued NPDES permits.

Steve W. Tedder cc: Preston Howard

RTH CAROLINA

NEW RIVER

APPENDIX IV. Stream classifications for the New River and its tributaries.

Name of Stream	Description	Class
New River	From source to Blue Creek	С
	From Blue Creek to Atlantic Coast Line Railroad Trestle	SB
	From Atlantic Coast Line Railroad Trestle to Grey Point	SC
	From Grey Point to Atlantic Ocean	SA
Blue Creek	From source to New River	SC
Brinson Creek	From source to New River	SC
Wilson Bay	Entire bay	SC
Northeast Creek	From source to New River	SC
Little Northeast Creek	From source to Northeast Creek	С
Southwest Creek	From source to New River	С
Morgan Bay	Entire bay	SC
Wallace Creek	From source to New River	SB

Description of classifications (Title 15A: 2B .0101)

No.

Class C:	freshwater protected for secondary recreation, fishing and aquatic life
	including propagation and survival; all freshwaters are classified to
	protect these uses at a minimum.
Class SC:	saltwaters protected for secondary recreation, fishing and aquatic life
	including propagation and survival; all saltwaters are classified to protect
	these uses at a minimum.
Class SB:	saltwaters protected for primary recreation which includes swimming on
	a frequent and/or organized basis and all Class SC uses.
Class SA:	suitable for commercial shellfishing and all other tidal saltwater uses.
